(54) Title: NUCLEOTIDE SEQUENCES OF CANOLA AND SOYBEAN PALMITOYL-ACP THIOESTERASE GENES AND THEIR USE IN THE REGULATION OF FATTY ACID CONTENT OF THE OILS OF SOYBEAN AND CANOLA PLANTS

(57) Abstract

Nucleotide sequences have been isolated that encode a C16 specific ACP thioesterase. The instant nucleotide sequences are expressed in E. coli and plant tissue. These sequences have been used in the anti-sense inhibition of endogenous plant thioesterase and in the regulation of the acyl co-enzyme A pool for the reduction of saturated fatty acid content in vegetable oil.

TITLE

NUCLEOTIDE SEQUENCES OF CANOLA
AND SOYBEAN PALMITOYL-ACP THIOESTERASE GENES
AND THEIR USE IN THE REGULATION OF FATTY ACID
CONTENT OF THE OILS OF SOYBEAN AND CANOLA PLANTS

FIELD OF INVENTION

The invention relates to the preparation and use of nucleic acid fragments encoding acyl-acyl carrier protein thioesterase enzymes to modify plant lipid composition. Chimeric genes incorporating such nucleic acid fragments and suitable regulatory sequences may be used to create transgenic plants with altered levels of saturated fatty acids.

BACKGROUND OF THE INVENTION

15 Plant lipids have a variety of industrial and nutritional uses and are central to plant membrane function and climatic adaptation. These lipids represent a vast array of chemical structures, and these structures determine the physiological and 20 industrial properties of the lipid. Many of these structures result either directly or indirectly from metabolic processes that alter the degree of saturation of the lipid.

Plant lipids find their major use as edible oils 25 in the form of triacylglycerols. The specific performance and health attributes of edible oils are determined largely by their fatty acid composition. Most vegetable oils derived from commercial plant varieties are composed primarily of palmitic (16:0), stearic (18:0), oleic (18:1), linoleic (18:2) and 30 linolenic (18:3) acids. Palmitic and stearic acids are, respectively, 16- and 18-carbon-long, saturated fatty acids. Oleic, linoleic, and linolenic acids are 18-carbon-long, unsaturated fatty acids containing one, two, and three double bonds, respectively. Oleic acid is referred to as a mono-unsaturated fatty acid, while linoleic and linolenic acids are referred to as poly-unsaturated fatty acids. The relative amounts of

saturated and unsaturated fatty acids commonly used, edible vegetable oils are summarized below (Table 1):

TABLE 1

Percentages of Saturated and Unsaturated Fatty
Acids in the Oils of Selected Oil Crops

	Saturated	Mono-unsaturated	Poly-unsaturated
Canola	6%	58%	36%
Soybean	15%	24%	61%
Corn	13%	25%	62%
Peanut	18%	48%	34%
Safflower	9% .	13%	78%
Sunflower	9%	41%	51%
Cotton	30%	19%	51%

Many recent research efforts have examined the role that saturated and unsaturated fatty acids playin reducing the risk of coronary heart disease. the past, it was believed that mono-unsaturates, in contrast to saturates and poly-unsaturates, had no effect on serum cholesterol and coronary heart disease 10 risk. Several recent human clinical studies suggest that diets high in mono-unsaturated fat and low in 'saturated fat may reduce the "bad" (low-density lipoprotein) cholesterol while maintaining the "good" (high-density lipoprotein) cholesterol (Mattson et 15 al., Journal of Lipid Research (1985) 26:194-202). Soybean oil is high in saturated fatty acids when compared to other sources of vegetable oil and contains a low proportion of oleic acid, relative to the total fatty acid content of the soybean seed. These characteristics do not meet important health needs as defined by the American Heart Association.

A soybean oil low in total saturates and polyunsaturates and high in monounsaturate would provide significant health benefits to the United States population, as well as, economic benefit to oil processors.

30

35

Oil bio. Thesis in plants has been orly well-studied [see Harwood (1989) in Critical Reviews in Plant Sciences, Vol. 8 (1):1-43]. The biosynthesis of palmitic, stearic and oleic acids occur in the plastids by the interplay of three key enzymes of the "ACP track": palmitoyl-ACP elongase, stearoyl-ACP desaturase and the acyl-ACP thioesterases.

Of these three enzyme types, the acyl-ACP thioesterases function to remove the acyl chain from the carrier protein (ACP) and thus from the metabolic 10 pathway. The oleoy-ACP thioesterase catalyzes the hydrolysis of oleoyl-ACP thioesters at high rates and at much lower rates the hydrolysis of palmitoyl-ACP and stearoyl-ACP. This multiple activity leads to substrate competition between enzymes and it is the 15 competition of this acyl-ACP thioesterase and palmitoyl-ACP elongase for the same substrate and of acyl-ACP thioesterase and stearoyl-ACP desaturase for the same substrate that leads to a portion of the 20 production of the palmitic and stearic acids found in the triacylglyceride of vegetable oils.

Once removed from the ACP track fatty acids are exported to the cytoplasm and there used to synthesize acyl-coenzyme A. These acyl-CoA's are the acyl donors for at least three different glycerol acylating enzymes (glycerol-3-P acyltransferase, 1-acyl-glycerol-3-P acyltransferase and diacylglycerol acyltransferase) which incorporate the acyl moieties into triacylglycerides during oil biosynthesis.

These acyltransferases show a strong, but not absolute, preference for incorporating saturated fatty acids at positions 1 and 3 and monounsaturated fatty acid at position 2 of the triglyceride. Thus, altering the fatty acid composition of the acyl pool will drive by mass action a corresponding change in the fatty acid composition of the oil.

Based on the above discussion, one approach to altering the levels of palmitic, stearic and oleic

5

10

15

20

25

30

acids in getable oils is by altering heir levels in the cytoplasmic acyl-CoA pool used for oil biosynthesis.

In previous work (WO 9211373) Applicant has demonstrated that oleoyl-ACP thioesterase may be modulated using cloned cDNA encoding the soybean enzyme. Oleoyl-ACP thioesterase cDNA was used to form chimeric genes for the transformation of soybean plant cells resulting in the anti-sense inhibition of acyl-ACP thioesterase in the plant seed.

Applicant has now discovered an entirely new plant thioesterase with activity on a C16 substrate that is also useful for the regulation of the acyl coenzyme A pool. Applicant has isolated nucleic acid fragments that encode soybean and canola palmitoyl-ACP thioesterases that are useful in modifying fatty acid composition in oil-producing species by genetic transformation. Thus, transfer of the nucleic acid fragments of the invention or a part thereof that encodes a functional enzyme, along with suitable regulatory sequences that direct the transcription of their mRNA, into a living cell will result in the production or over-production of palmitoyl-ACP thioesterases and will result in increased levels of saturated fatty acids in cellular lipids, including triacylglycerols.

Transfer of the nucleic acid fragments of the invention or a part thereof, along with suitable regulatory sequences that direct the transcription of their anti-sense RNA, into plants will result in the inhibition of expression of the endogenous palmitoyl-ACP thioesterase that is substantially homologous with the transferred nucleic acid fragment and will result in decreased levels of saturated fatty acids in cellular lipids, including triacylglycerols.

Transfer of the nucleic acid fragments of the invention or a part thereof, along with suitable regulatory sequences that direct the transcription of

their mRNA, it plants may result in inhittion by cosuppression of the expression of the endogenous palmitoyl-ACP thioesterase gene that is substantially homologous with the transferred nucleic acid fragment and may result in decreased levels of unsaturated fatty acids in cellular lipids, including triacylglycerols.

SUMMARY OF THE INVENTION

A means to control the levels of saturated and unsaturated fatty acids in edible plant oils has been discovered. Utilizing the soybean seed palmitoyl-ACP thioesterase cDNA, for either the precursor or enzyme, chimeric genes are created and may be utilized to transform soybean plants to produce seed oils with reduced levels of saturated fatty acids. Similarly the canola seed palmitoyl-ACP thioesterase cDNA for either the precursor or enzyme may be utilized to create chimeric genes and these genes may then be used to transform canola plants to produce seed oils with reduced levels of saturated fatty acids.

10

15

20

25

30

35

Specifically, one aspect of the present invention is a nucleic acid fragment comprising a nucleotide sequence encoding the soybean seed palmitoyl-ACP thioesterase cDNA corresponding to nucleotides 1 to 1688 in the sequence shown in Sequence Description SEQ ID NO:1, or any nucleic acid fragment substantially homologous therewith. In addition, another aspect involves a nucleic acid fragment comprising a nucleotide sequence encoding the canola seed palmitoyl-ACP thioesterase cDNA corresponding to the nucleotides 1 to 1488 in the Sequence Description SEO ID NO:2, nucleotides 1 to 1674 in the Sequence Description SEQ ID NO:31 or any nucleic acid fragment substantially homologous therewith. Preferred are those nucleic acid fragments encoding the soybean seed palmitoyl-ACP thioesterase precursor, the mature soybean seed palmitoyl-ACP thioesterase enzyme, the canola seed palmitoyl-ACP thioesterase precursor, and

the matur canola seed palmitoyl-ACP cesterase enzyme.

Another aspect of this invention involves a chimeric gene capable of transforming a soybean plant cell comprising a nucleic acid fragment encoding the soybean seed palmitoyl-ACP thioesterase cDNA of Sequence ID 1 operably linked to suitable regulatory sequences producing anti-sense inhibition of soybean seed palmitoyl-ACP thioesterase in the seed or linked suitably to produce sense expression of the soybean seed palmitoyl-ACP thioesterase gene resulting in either over expression of the palmitoyl-ACP thioesterase protein or under expression of the palmitoyl-ACP thioesterase protein when co-suppression occurs. Preferred are those chimeric genes which incorporate nucleic acid fragments encoding soybean seed palmitoyl-ACP thioesterase precursor or mature soybean seed palmitoyl-ACP thioesterase enzyme.

10

15

20

25

35

Yet another embodiment of the invention involves a method of producing seed oil containing either elevated or reduced levels of saturated fatty acids comprising: (a) transforming a soybean plant cell with a chimeric gene described above, (b) growing sexually mature plants from said transformed plant cells, (c) screening progeny seeds from said sexually mature plants for the desired levels of palmitic and stearic acid, and (d) crushing said progeny seed to obtain said oil containing decreased levels of palmitic and stearic acid. Preferred methods of transforming such plant cells would include the use of 30 Ti and Ri plasmids of Agrobacterium, electroporation, and high-velocity ballistic bombardment.

Another aspect of this invention involves a chimeric gene capable of transforming a canola plant cell comprising a nucleic acid fragment encoding the canola seed palmitoyl-ACP thioesterase cDNA of Sequence ID 2 or Sequence ID 31 operably linked to suitable regulatory sequences producing anti-sense

inhibition of conola seed palmitoyl-ACP the esterase in the seed or linked suitably to produce sense expression of the canola seed palmitoyl-ACP thioesterase gene resulting in either over expression of the palmitoyl-ACP thioesterase protein or under expression of the palmitoyl-ACP thioesterase protein when co-suppression occurs. Preferred are those chimeric genes which incorporate nucleic acid fragments encoding canola seed palmitoyl-ACP thioesterase precursor or mature canola seed palmitoyl-ACP thioesterase enzyme.

Sequence Descriptions SEQ ID NOs:1 and 2 show the nucleotide sequences of the soybean seed palmitoyl-ACP thioesterase cDNA and the canola seed palmitoyl-ACP thioesterase cDNA respectively.

DETAILED DESCRIPTION OF THE INVENTION

In the context of this disclosure, a number of terms shall be used.

Fatty acids are specified by the number of carbon 20 atoms and the number and position of the double bond: the numbers before and after the colon refer to the chain length and the number of double bonds, respectively. The number following the fatty acid designation indicates the position of the double bond from the carboxyl end of the fatty acid with the "c" 25 affix for the cis-configuration of the double bond. For example, palmitic acid (16:0), stearic acid (18:0), oleic acid (18:1,9c), petroselinic acid (18:1, 6c), linoleic acid (18:2,9c,12c), g-linolenic acid 30 (18:3, 6c,9c,12c) and a-linolenic acid (18:3, 9c, 12c, 15c). Unless otherwise specified 18:1, 18:2 and 18:3 refer to oleic, linoleic and linolenic fatty acids. The term "palmitoyl-ACP thioesterase" used herein refers to an enzyme which catalyzes the hydrolytic cleavage of the carbon-sulfur thioester 35 bond in the pantothene prosthetic group of palmitoylacyl carrier protein as its preferred reaction. Hydrolysis of other fatty acid-acyl carrier protein

thioesters ay also be catalyzed by the enzymes. term "nucleic acid" refers to a large molecule which can be single-stranded or double-stranded, composed of monomers (nucleotides) containing a sugar, a phosphate and either a purine or pyrimidine. A "nucleic acid fragment" is a fraction of a given nucleic acid molecule. In higher plants, deoxyribonucleic acid (DNA) is the genetic material while ribonucleic acid (RNA) is involved in the transfer of the information in DNA into proteins. A "genome" is the entire body 10 of genetic material contained in each cell of an The term "nucleotide sequence" refers to the sequence of DNA or RNA polymers, which can be single- or double-stranded, optionally containing synthetic, non-natural or altered nucleotide bases 15 capable of incorporation into DNA or RNA polymers. The term "oligomer" refers to short nucleotide sequences, usually up to 100 bases long. As used herein, the term "homologous to" refers to the relatedness between the nucleotide sequence of two 20 nucleic acid molecules or between the amino acid sequences of two protein molecules. Estimates of such homology are provided by either DNA-DNA or DNA-RNA hybridization under conditions of stringency as is well understood by those skilled in the art (Hames and 25 Higgins, Eds. (1985) Nucleic Acid Hybridisation, IRL Press, Oxford, U.K.); or by the comparison of sequence similarity between two nucleic acids or proteins, such as by the method of Needleman et al. (J. Mol. Biol. (1970) 48:443-453). As used herein, "substantially 30 homologous" refers to nucleotide sequences that have more than 90% overall identity at the nucleotide level with the coding region of the claimed sequence, such as genes and pseudo-genes corresponding to the coding regions. The nucleic acid fragments described herein 35 include molecules which comprise possible variations, both man-made and natural, such as but not limited to (a) those that involve base changes that do not cause

20

25

30

35

a change in an encoded amino acid, or (b) which involve base changes that alter an amino acid but do not affect the functional properties of the protein encoded by the DNA sequence, (c) those derived from deletions, rearrangements, amplifications, random or controlled mutagenesis of the nucleic acid fragment, and (d) even occasional nucleotide sequencing errors.

"Gene" refers to a nucleic acid fragment that expresses a specific protein, including regulatory sequences preceding (5' non-coding) and following (3' non-coding) the coding region. "Native" gene refers to an isolated gene with its own regulatory sequences as found in nature. "Chimeric gene" refers to a gene that comprises heterogeneous regulatory and coding sequences not found in nature. "Endogenous" gene refers to the native gene normally found in its natural location in the genome and is not isolated. A "foreign" gene refers to a gene not normally found in the host organism but that is introduced by gene transfer. "Pseudo-gene" refers to a genomic nucleotide sequence that does not encode a functional enzyme.

"Coding sequence" refers to a DNA sequence that codes for a specific protein and excludes the non-coding sequences. It may constitute an "uninterrupted coding sequence", i.e., lacking an intron or it may include one or more introns bounded by appropriate splice junctions. An "intron" is a nucleotide sequence that is transcribed in the primary transcript but that is removed through cleavage and re-ligation of the RNA within the cell to create the mature mRNA that can be translated into a protein.

"Initiation codon" and "termination codon" refer to a unit of three adjacent nucleotides in a coding sequence that specifies initiation and chain termination, respectively, of protein synthesis (mRNA translation). "Open reading frame" refers to the coding sequence uninterrupted by introns between

initiatio and termination codons that encodes an amino acid sequence.

"RNA transcript" refers to the product resulting from RNA polymerase-catalyzed transcription of a DNA sequence. When the RNA transcript is a perfect 5 complementary copy of the DNA sequence, it is referred to as the primary transcript or it may be a RNA sequence derived from posttranscriptional processing of the primary transcript and is referred to as the "Messenger RNA (mRNA)" refers to the RNA 10 mature RNA. that is without introns and that can be translated into protein by the cell. "cDNA" refers to a doublestranded DNA that is complementary to and derived from mRNA. "Sense" RNA refers to RNA transcript that includes the mRNA. "Antisense RNA" refers to a RNA 15 transcript that is complementary to all or part of a target primary transcript or mRNA and that blocks the expression of a target gene by interfering with the processing, transport and/or translation of its primary transcript or mRNA. The complementarity of an 20 antisense RNA may be with any part of the specific gene transcript, i.e., at the 5' non-coding sequence, 3' non-coding sequence, introns, or the coding sequence. In addition, as used herein, antisense RNA may contain regions of ribozyme sequences that 25 increase the efficacy of antisense RNA to block gene "Ribozyme" refers to a catalytic RNA and expression. includes sequence-specific endoribonucleases.

As used herein, "suitable regulatory sequences" refer to nucleotide sequences in native or chimeric genes that are located upstream (5'), within, and/or downstream (3') to the nucleic acid fragments of the invention, which control the expression of the nucleic acid fragments of the invention. The term "expression", as used herein, refers to the transcription and stable accumulation of the sense (mRNA) or the antisense RNA derived from the nucleic acid fragment(s) of the invention that, in conjunction

30

35

WO 96/06936

PCT/US95/10627

with the proton apparatus of the cell, realts in altered levels of the palmitoyl-ACP thioesterase. Expression or overexpression of the gene involves transcription of the gene and translation of the mRNA into precursor or mature palmitoyl-ACP thioesteras proteins. "Antisense inhibition" refers to the production of antisense RNA transcripts capable of preventing the expression of the target protein. "Overexpression" refers to the production of a gene product in transgenic organisms that exceeds levels of 10 production in normal or non-transformed organisms. "Cosuppression" refers to the expression of a foreign gene which has substantial homology to an endogenous gene resulting in the suppression of expression of 15 both the foreign and the endogenous gene. "Altered levels" refers to the production of gene product(s) in transgenic organisms in amounts or proportions that differ from that of normal or non-transformed organisms.

20 "Promoter" refers to a DNA sequence in a gene, usually upstream (5') to its coding sequence, which controls the expression of the coding sequence by providing the recognition for RNA polymerase and other factors required for proper transcription. 25 artificial DNA constructs promoters can also be used to transcribe antisense RNA. Promoters may also contain DNA sequences that are involved in the binding of protein factors which control the effectiveness of transcription initiation in response to physiological 30 or developmental conditions. It may also contain enhancer elements. An "enhancer" is a DNA sequence which can stimulate promoter activity. It may be an innate element of the promoter or a heterologous element inserted to enhance the level and/or tissuespecificity of a promoter. "Constitutive promoters" 35 refers to those that direct gene expression in all tissues and at all times. "Tissue-specific" or "development-specific" promoters as referred to herein

5

10

15

20

.25

30

35

exclusively in specific tissues, such as leaves or seeds, or at specific development stages in a tissue, such as in early or late embryogenesis, respectively.

The "3' non-coding sequences" refers to the DNA sequence portion of a gene that contains a polyadenylation signal and any other regulatory signal capable of affecting mRNA processing or gene expression. The polyadenylation signal is usually characterized by affecting the addition of polyadenylic acid tracts to the 3' end of the mRNA precursor.

"Transformation" herein refers to the transfer of a foreign gene into the genome of a host organism and its genetically stable inheritance. "Restriction fragment length polymorphism" refers to different sized restriction fragment lengths due to altered nucleotide sequences in or around variant forms of genes. "Fertile" refers to plants that are able to propagate sexually.

"Plants" refer to photosynthetic organisms, both eukaryotic and prokaryotic, whereas the term "Higher plants" refers to eukaryotic plants. "Oil-producing species" herein refers to plant species which produce and store triacylglycerol in specific organs, primarily in seeds. Such species include soybean (Glycine max), rapeseed and canola (including Brassica napus, B. campestris), sunflower (Helianthus annus), cotton (Gossypium hirsutum), corn (Zea mays), cocoa (Theobroma cacao), safflower (Carthamus tinctorius), oil palm (Elaeis guineensis), coconut palm (Cocos nucifera), flax (Linum usitatissimum), castor (Ricinus communis) and peanut (Arachis hypogaea). The group also includes non-agronomic species which are useful in developing appropriate expression vectors such as tobacco, rapid cycling Brassica species, and Arabidopsis thaliana, and wild species which may be a source of unique fatty acids.

WO 96/06936

"Sequence ependent protocols" refer

techniques that rely on a nucleotide sequence for
their utility. Examples of sequence-dependent
protocols include, but are not limited to, the methods
of nucleic acid and oligomer hybridization and methods
of DNA and RNA amplification such as are exemplified
in various uses of the polymerase chain reaction
(PCR).

PCT/US95/10627

"PCR" or "polymerase chain reaction" will refer
to a method that results in the linear or logarithmic
amplification of nucleic acid molecules. PCR
generally requires a replication composition
consisting of, for example, nucleotide triphosphates,
two primers with appropriate sequences, DNA or RNA
polymerase and proteins. These reagents and details
describing procedures for their use in amplifying
nucleic acids are provided in U.S. Patent 4,683,202
(1987, Mullis, et al.) and U.S. Patent 4,683,195
(1986, Mullis, et al.).

20 The present invention describes two nucleic acid fragments that encode soybean and canola seed palmitoyl-ACP thioesterases. These enzymes catalyze the hydrolytic cleavings of palmitic acid, stearic acid and oleic acid from ACP in the respective acyl-25 ACPs. Transfer of one or both of these nucleic acid fragments of the invention or a part thereof that encodes a functional enzyme, with suitable regulatory sequences into a living cell will result in the production or over-production of palmitoly-ACP thioesterase, which may result in increased levels of 30 palmitic and to a lesser extent, stearic acids in cellular lipids, including oil.

Transfer of the nucleic acid fragment or fragments of the invention, with suitable regulatory sequences that transcribe the present cDNA, into a plant which has an endogenous seed palmitoyl-ACP thioesterase that is substantially homogeneous with the present cDNA may result in inhibition by co-

suppression of the entogenous palmitoyl-ACP thioesterase gene and, consequently, in a decreased amount of palmitic and to a lesser extent stearic acids in the seed oil.

Transfer of the nucleic acid fragment or fragments of the invention into a soybean or canola plants with suitable regulatory sequences that transcribe the anti-sense RNA complementary to the mRNA, or its precursor, for seed palmitoyl-ACP thioesterase may result in the inhibition of the expression of the endogenous palmitoyl-ACP thioesterase gene and, consequently, in reduced amounts of palmitic and to a lesser extent stearic acids in the seed oil.

5

20

30

35

The nucleic acid fragments of the invention can also be used as a restriction fragment length polymorphism markers in soybean and canola genetic studies and breeding programs.

Identification and isolation of soybean and canola palmitoyl-ACP thioesterase coding cDNA

In order to identify cDNA encoding for palmitoyl-ACP thioesterase in both soybean and canola it was first necessary to construct a probe suitable for screening cDNA libraries from these plant genomes. A portion of the Arabidopis cDNA known to have significant homology with an Umbellularia C12:0-ACP thioesterase was used to design PCR primers (SEQ ID NO:3 and 4). Polysomal RNA was isolated and purified from Arabidopis and used as a template for RNA-PCR (GeneAmp® PNA-PCR kit Perkin Elmer Cetus, part number N808-0017). Using this method a 560 bp fragment was generated, and radiolabeled to be used as a probe for screening soybean and canola cDNA libraries.

Methods of creating cDNA libraries from eukaryotic genomes are well known in the art (see, for example, Sambrook, et al. (Molecular Cloning, A Laboratory Manual, 2nd ed. (1989), Cold Spring Harbor Laboratory Press). In a preferred method total RNA is

15

isolated (Kan Lay et al., (Cell (1980) 19 5-946) and polyadenylated mRNA is purified by standard means. mRNA is incorporated into a suitable phage such as lambda phage and used to transform a suitable host such as E. coli. Transformed clones are screened for positively hybridizing plaques using the radiolabelled, PCR derived probe.

In this manner DNA fragments were selected from both soybean and canola that had potential for encoding an acyl-ACP thioesterase. The DNA fragment isolated from soybean is identified as SEQ ID NO:1 and the DNA fragments isolated from canola are identified as SEQ ID NO:2 and SEQ ID NO:31.

Expression of soybean and canola acyl-ACP Thioesterase encoding DNA in E. coli

In order to verify the function of the isolated soybean and canola DNA fragments it was necessary to express the fragments in recombinant hosts for protein purification and analysis of enzyme activity.

20 The present invention provides vectors and host cells suitable for genetic manipulations and the expression of recombinant proteins. Suitable hosts may include a variety of gram negative and gram positive bacteria where E. coli is generally 25 preferred. Examples of bacteria-derived vectors include plasmid vectors such as pBR322, pUC19, pSP64. pUR278 and pORF1. Illustrative of suitable viral vectors are those derived from phage, vaccinia, and a variety of viruses. Examples of phage vectors include 1+, 1EMBL3, 12001, 1gt10, 1gt11, Charon 4a, Charon 40, 30 and lZAP/R. pXB3 and pSCll are exemplary of vaccinia vectors (Chakrabarti et al., Molec. Cell. Biol. 5:3401-9 (1985) and Mackett et al. J. Virol. 49:857864 (1984). Preferred in the present invention are the bacteria derived vectors such as pET-3d (described by 35 F. W. Studier, A. H. Rosenberg, J. J. Dunn and J. W. Dubendorff, Methods in Enzymology Vol. 185) and the

host E. coli strain BL21 (DE3) (pLysE).

Once ditable vectors are constructed they are used to transform suitable bacterial hosts.

Introduction of desired DNA fragments into E. coli may be accomplished by known procedures such as by transformation, e.g., using calcium-permeabilized cells, electroporation, or by transfection using a recombinant phage virus. (Sambrook et al., supra.)

For the expression of the soybean and canola DNA fragments (SEQ ID NO:1 and 2, respectively) the fragments were first cut with the appropriate restriction enzymes for the isolation of the region encoding the mature protein. Following this the restriction fragments were ligated to an appropriate linker sequence and inserted into a suitable vector downstream of an appropriate promoter. Suitable promoters may be either inducible or constitutive and are preferably derived from bacteria. Examples of suitable promoters are T7 and lac.

Thioesterase assay:

10

15

Methods for the measurement of thioesterase 20 activity are known in the art (see, for example, Smith et al., Biochem, J. 212, 155, (1983) and Spencer et al., J. Biol. Chem., 253, 5922, (1978)). For the purpose of the present invention a modification of the method of Mckeon and Stumpf [J. Biol. Chem. (1982) 257:12141-12147] was used involving the synthesis of radiolabelled substrate ([14C]acyl-ACP) using ACP and ACP synthetase isolated from E. coli. Solutions of [14C] palmitic acid, [14C] stearic acid, [14C] oleic acid, [14C] lauric acid, and [14C] decanoic acid were 30 added to purified ACP in the presence of ACP synthetase and the resulting radiolabelled acyl ACP was purified by standard methods. Activity of the protein encoded and expressed by SEQ ID NO:1 and SEQ ID NO:2 was measured on the basis of the amount of 35 [14C] substrate that was hydrolyzed.

Inhibition of ant Target Genes by Use of Atisense RNA

Antisense RNA has been used to inhibit plant target genes in a tissue-specific manner (see van der Krol et al., Biotechniques (1988) 6:958-976). Antisense inhibition has been shown using the entire cDNA sequence (Sheehy et al., Proc. Natl. Acad. Sci. USA (1988) 85:8805-8809) as well as a partial cDNA sequence (Cannon et al., Plant Molec. Biol. (1990) 15:39-47). There is also evidence that the 3' non-10 coding sequences (Ch'ng et al., Proc. Natl. Acad. Sci. USA (1989) 86:10006-10010) and fragments of 5' coding sequence, containing as few as 41 base-pairs of a 1.87 kb cDNA (Cannon et al., Plant Molec. Biol. (1990) 15:39-47), can play important roles in anti-sense 15 inhibition.

The entire soybean palmitoyl-ACP thioesterase cDNA was cloned in the anti-sense orientation with respect to a soybean β-conglycinin promoter and the chimeric gene transformed into soybean somatic embryos. As demonstrated in Example 2, these embryos serve as good model system for soybean zygotic embryos. Transformed somatic embryos showed inhibition of palmitate and possibly stearate biosyntheis. Similarly, the entire Brassica napus palmitoyl-ACP cDNA was cloned in the anti-sense orientation with respect to a rapeseed napin promoter and the chimeric gene transformed into B. napus. Inhibition of Plant Target Genes by Cosuppression

The phenomenon of cosuppression has also been used to inhibit plant target genes in a tissue-specific manner. Cosuppression of an endogenous gene using the entire cDNA sequence (Napoli et al., The Plant Cell (1990) 2:279-289; van der Krol et al., The Plant Cell (1990) 2:291-299) as well as a partial cDNA sequence (730 bp of a 1770 bp cDNA) (Smith et al., Mol. Gen. Genetics (1990) 224:477-481) are known.

The cleic acid fragments of the instant invention encoding palmitoyl-ACP thioesterases or parts thereof, with suitable regulatory sequences, can be used to reduce the level of palmitoyl-ACP

thioesterase, thereby altering fatty acid composition, in transgenic plants which contain an endogenous gene substantially homologous to the introduced nucleic acid fragment. The experimental procedures necessary for this are similar to those described above for the anti-sense expression of palmitoyl-ACP thioesterase nucleic acid fragments except that one may use a either whole or partial cDNA.

Endogenous genes can also be inhibited by non-coding regions of an introduced copy of the gene [for example, Brusslan, J. A., et al. (1993) Plant Cell 5:667-677; Matzke, M. A. et al Plant Molecular Biology 16:821-830].

Selection of Hosts, Promoters and Enhancers

5

10

15

35

A preferred class of heterologous hosts for the
expression of the nucleic acid fragments of the
invention are eukaryotic hosts, particularly the cells
of higher plants. Particularly preferred among the
higher plants are the oil-producing species, such as
soybean (Glycine max), rapeseed (including Brassica

25 napus, B. campestris), sunflower (Helianthus annus),
cotton (Gossypium hirsutum), corn (Zea mays), cocoa
(Theobroma cacao), safflower (Carthamus tinctorius),
oil palm (Elaeis guineensis), coconut palm (Cocos
nucifera), flax (Linum usitatissimum), and peanut

30 (Arachis hypogaea).

Expression in plants will use regulatory sequences functional in such plants. The expression of foreign genes in plants is well-established (De Blaere et al., Meth. Enzymol. (1987) 153:277-291). The source of the promoter chosen to drive the expression of the fragments of the invention is not critical provided it has sufficient transcriptional activity to accomplish the invention by increasing or

decreasing, receively, the level of transatable mRNA for the fatty acid desaturases in the desired host tissue. Preferred promoters include (a) strong constitutive plant promoters, such as those directing the 19S and 35S transcripts in cauliflower mosaic virus (Odell et al., Nature (1985) 313:810-812; Hull et al., Virology (1987) 86:482-493), (b) tissue- or developmentally-specific promoters, and (c) other transcriptional promoter systems engineered in plants, such as those using bacteriophage T7 RNA polymerase 10 promoter sequences to express foreign genes. Examples of tissue-specific promoters are the light-inducible promoter of the small subunit of ribulose 1,5-bisphosphate carboxylase (if expression is desired in photosynthetic tissues), the maize zein protein 15 promoter (Matzke et al., EMBO J. (1984) 3:1525-1532), and the chlorophyll a/b binding protein promoter (Lampa et al., Nature (1986) 316:750-752).

Particularly preferred promoters are those that allow seed-specific expression. This may be 20 especially useful since seeds are the primary source of vegetable oils and also since seed-specific expression will avoid any potential deleterious effect in non-seed tissues. Examples of seed-specific promoters include, but are not limited to, the 25 promoters of seed storage proteins, which can represent up to 90% of total seed protein in many plants. The seed storage proteins are strictly regulated, being expressed almost exclusively in seeds in a highly tissue-specific and stage-specific manner 30 (Higgins et al., Ann. Rev. Plant Physiol. (1984) 35:191-221; Goldberg et al., Cell (1989) 56:149-160). Moreover, different seed storage proteins may be expressed at different stages of seed development.

Expression of seed-specific genes has been studied in great detail (see reviews by Goldberg et al., Cell (1989) 56:149-160 and Higgins et al., Ann. Rev. Plant Physiol. (1984) 35:191-221). There

35

are currency numerous examples of seed specific expression of seed storage protein genes in transgenic dicotyledonous plants. These include genes from dicotyledonous plants for bean b-phaseolin (Sengupta-Gopalan et al., Proc. Natl. Acad. Sci. USA (1985) 82:3320-3324; Hoffman et al., Plant Mol. Biol. (1988) 11:717-729), bean lectin (Voelker et al., EMBO J. (1987) 6:3571-3577), soybean lectin (Okamuro et al., Proc. Natl. Acad. Sci. USA (1986) 83:8240-8244), soybean Kunitz trypsin inhibitor (Perez-Grau et al., 10 Plant Cell (1989) 1:095-1109), soybean b-conglycinin (Beachy et al., EMBO J. (1985) 4:3047-3053; pea vicilin (Higgins et al., Plant Mol. Biol. (1988) 11:683-695), pea convicilin (Newbigin et al., Planta 15 (1990) 180:461-470), pea legumin (Shirsat et al., Mol. Gen. Genetics (1989) 215:326-331); rapeseed napin (Radke et al., Theor. Appl. Genet. (1988) 75:685-694) as well as genes from monocotyledonous plants such as for maize 15 kD zein (Hoffman et al., EMBO J. (1987) 6:3213-3221), maize 18 kD oleosin (Lee et al., Proc. 20 Natl. Acad. Sci. USA (1991) 888:6181-6185), barley b-hordein (Marris et al., Plant Mol. Biol. (1988) 10:359-366) and wheat glutenin (Colot et al., EMBO J. (1987) 6:3559-3564). Moreover, promoters of seedspecific genes operably linked to heterologous coding 25 sequences in chimeric gene constructs also maintain their temporal and spatial expression pattern in transgenic plants. Such examples include use of Arabidopsis thaliana 2S seed storage protein gene promoter to express enkephalin peptides in Arabidopsis 30 and B. napus seeds (Vandekerckhove et al., Bio/Technology (1989) 7:929-932), bean lectin and bean b-phaseolin promoters to express luciferase (Riggs et al., Plant Sci. (1989) 63:47-57), and wheat glutenin promoters to express chloramphenicol acetyl 35 transferase (Colot et al., EMBO J. (1987) 6:3559-3564).

Of partial ar use in the expression nucleic acid fragment of the invention will be the heterologous promoters from several soybean seed storage protein genes such as those for the Kunitz trypsin inhibitor (Jofuku et al., Plant Cell (1989) 1:1079-1093; glycinin (Nielson et al., Plant Cell (1989) 1:313-328), and b-conglycinin (Harada et al., Plant Cell (1989) 1:415-425). Promoters of genes for a- and b-subunits of soybean b-conglycinin storage protein will be particularly useful in expressing the 10 mRNA or the antisense RNA in the cotyledons at mid-to late-stages of seed development (Beachy et al., EMBO J. (1985) 4:3047-3053) in transgenic plants. This is because there is very little position effect on their 15 expression in transgenic seeds, and the two promoters show different temporal regulation. The promoter for the a-subunit gene is expressed a few days before that for the b-subunit gene. This is important for transforming rapeseed where oil biosynthesis begins about a week before seed storage protein synthesis 20 (Murphy et al., J. Plant Physiol. (1989) 135:63-69).

Also of particular use will be promoters of genes expressed during early embryogenesis and oil biosynthesis. The native regulatory sequences, including the native promoters, of the palmitoyl-ACP 25 thioesterase genes expressing the nucleic acid fragments of the invention can be used following their isolation by those skilled in the art. Heterologous promoters from other genes involved in seed oil biosynthesis, such as those for B. napus isocitrate lyase and malate synthase (Comai et al., Plant Cell (1989) 1:293-300), delta-9 desaturase from safflower (Thompson et al. Proc. Natl. Acad. Sci. USA (1991) 88:2578-2582) and castor (Shanklin et al., Proc. Natl. Acad. Sci. USA (1991) 88:2510-2514), acyl carrier 35 protein (ACP) from <u>Arabidopsis</u> (Post-Beittenmiller et al., Nucl. Acids Res. (1989) 17:1777), B. napus (Safford et al., Eur. J. Biochem. (1988) 174:287-295),

and B. ca estris (Rose et al., Nucl. ids Res. (1987) 15:7197), b-ketoacyl-ACP synthetase from barley (Siggaard-Andersen et al., Proc. Natl. Acad. Sci. USA (1991) 88:4114-4118), and oleosin from Zea mays (Lee et al., Proc. Natl. Acad. Sci. USA (1991) 5 88:6181-6185), soybean (Genbank Accession No: X60773) and B. napus (Lee et al., Plant Physiol. (1991) 96:1395-1397) will be of use. If the sequence of the corresponding genes is not disclosed or their promoter region is not identified, one skilled in the art can 10 use the published sequence to isolate the corresponding gene and a fragment thereof containing the promoter. The partial protein sequences for the relatively-abundant enoyl-ACP reductase and acetyl-CoA carboxylase are also published (Slabas et al., 15 Biochim. Biophys. Acta (1987) 877:271-280; Cottingham et al., Biochim. Biophys. Acta (1988) 954:201-207) and one skilled in the art can use these sequences to isolate the corresponding seed genes with their promoters. Attaining the proper level of expression 20 of the nucleic acid fragments of the invention may require the use of different chimeric genes utilizing different promoters. Such chimeric genes can be transferred into host plants either together in a single expression vector or sequentially using more 25 than one vector.

It is envisioned that the introduction of enhancers or enhancer-like elements into the promoter regions of either the native or chimeric nucleic acid fragments of the invention will result in increased expression to accomplish the invention. This would include viral enhancers such as that found in the 35S promoter (Odell et al., Plant Mol. Biol. (1988) 10:263-272), enhancers from the opine genes (Fromm et al., Plant Cell (1989) 1:977-984), or enhancers from any other source that result in increased transcription when placed into a promoter operably linked to the nucleic acid fragment of the invention.

30

35

element isolated from the gene for the a-subunit of b-conglycinin that can confer 40-fold seed-specific enhancement to a constitutive promoter (Chen et al., Dev. Genet. (1989) 10:112-122). One skilled in the art can readily isolate this element and insert it within the promoter region of any gene in order to obtain seed-specific enhanced expression with the promoter in transgenic plants. Insertion of such an element in any seed-specific gene that is expressed at different times than the b-conglycinin gene will result in expression in transgenic plants for a longer period during seed development.

Any 3' non-coding region capable of providing a polyadenylation signal and other regulatory sequences that may be required for the proper expression of the nucleic acid fragments of the invention can be used to accomplish the invention. This would include 3' ends of the native fatty acid desaturase(s), viral genes such as from the 35S or the 19S cauliflower mosaic virus transcripts, from the opine synthesis genes, ribulose 1,5-bisphosphate carboxylase, or chlorophyll a/b binding protein. There are numerous examples in the art that teach the usefulness of different 3' non-coding regions.

Transformation Methods

10

Various methods of transforming cells of higher plants according to the present invention are available to those skilled in the art (see EPO Pub. 30 0 295 959 A2 and 0 318 341 A1). Such methods include those based on transformation vectors utilizing the Ti and Ri plasmids of Agrobacterium spp. It is particularly preferred to use the binary type of these vectors. Ti-derived vectors transform a wide variety of higher plants, including monocotyledonous and dicotyledonous plants (Sukhapinda et al., Plant Mol. Biol. (1987) 8:209-216; Potrykus, Mol. Gen. Genet. (1985) 199:183). Other transformation methods are

available those skilled in the art, the as direct uptake of foreign DNA constructs (see EPO Pub. 0 295 959 A2), techniques of electroporation (Fromm et al., Nature (1986) (London) 319:791) or high-velocity ballistic bombardment with metal particles coated with the nucleic acid constructs (Kline et al., Nature (1987) (London) 327:70). Once transformed, the cells can be regenerated by those skilled in the art.

Of particular relevance are the recently described methods to transform foreign genes into commercially important crops, such as rapeseed (De Block et al., Plant Physiol. (1989) 91:694-701), sunflower (Everett et al., Bio/Technology (1987) 5:1201), and soybean (Christou et al., Proc. Natl. Acad. Sci USA (1989) 86:7500-7504.

The present invention is further defined in the following Examples, in which all parts and percentages are by weight and degrees are Celsius, unless otherwise stated. It should be understood that these Examples, while indicating preferred embodiments of the invention, are given by way of illustration only. From the above discussion and these Examples, one skilled in the art can ascertain the essential characteristics of this invention, and without departing from the spirit and scope thereof, can make various changes and modifications of the invention to adapt it to various usages and conditions.

Thioesterase assay:

To assay for the presence of thioesterase

20 activity [14C] radiolabled acyl ACP substrates were
prepared. Preparation of the substrates required the
isolation of ACP and ACP synthetase from E. coli and
the enzymatic reaction of [14C] fatty acid with the ACP
protein.

25 Purification of Acyl Carrier Protein (ACP) from E. coli

To frozen E. coli cell paste, (0.5 kg of 1/2 log phase growth of E. coli B grown on minimal media and obtained from Grain Processing Corp, Muscatine, IA)

- was added 50 mL of a solution 1M in Tris, 1M in glycine, and 0.25 M in EDTA. Ten mL of 1M MgCl₂ was added and the suspension was thawed in a water bath at 50°C. As the suspension approached 37°C it was transferred to a 37°C bath, made to 10 mM in
- 2-mercaptoethanol and 20 mg of DNAse and 50 mg of lysozyme were added. The suspension was stirred for 2 h, then sheared by three 20 second bursts in a Waring Blendor. The volume was adjusted to 1 L and

the mixtul was centrifuged at 24,000x or 30 min. The resultant supernatant was centrifuged at 90,000xg for 2 h. The resultant high-speed pellet was saved for extraction of acyl-ACP synthase (see below) and the supernatant was adjusted to pH 6.1 by the addition of acetic acid. The extract was then made to 50% in 2-propanol by the slow addition of cold 2-propanol to the stirred solution at 0°C. The resulting precipitate was allowed to settle for 2 h and then removed by centrifugation at 16,000xg. The resultant 10 supernatant was adjusted to pH 6.8 with KOH and applied at 2 mL/min to a 4.4 x 12 cm column of DEAE-Sephacel which had been equilibrated in 10 mM MES, pH 6.8. The column was washed with 10 mM MES, pH 6.8 and eluted with 1 L of a gradient of LiCl from 0 to 15 1.7M in the same buffer. Twenty mL fractions were collected and the location of eluted ACP was determined by applying 10 µL of every second fraction to a lane of a native polyacrylamide (20% acrylamide) gel electrophoresis (PAGE). Fractions eluting at 20 about 0.7M LiCl contained nearly pure ACP and were combined, dialyzed overnight against water and then lyophilized.

Purification of Acyl-ACP Synthase

25

30

35

Membrane pellets resulting from the high-speed centrifugation described above were homogenized in 380 mL of 50 mM Tris-Cl, pH 8.0, and 0.5 M in NaCl and then centrifuged at 80,000xg for 90 min. The resultant supernatant was discarded and the pellets resuspended in 50 mM Tris-Cl, pH 8.0, to a protein concentration of 12 mg/mL. The membrane suspension was made to 2% in Triton X-100 and 10 mM in MgCl₂, and stirred at 0°C for 20 min before centrifugation at 80,000xg for 90 min. The protein in the resultant supernatant was diluted to 5 mg/mL with 2% Triton X-100 in 50 mM Tris-Cl, pH 8.0 and, then, made to 5 mM ATP by the addition of solid ATP (disodium salt) along with an equimolar amount of NaHCO₃. The solution was

30

35

warmed in a C bath until the internal Samperature reached 53°C and was then maintained at between 53°C and 55°C for 5 min. After 5 min the solution was rapidly cooled on ice and centrifuged at 15,000xg for 15 min. The supernatant from the heat treatment step was loaded directly onto a column of 7 mL Blue Sepharose 4B which had been equilibrated in 50 mM Tris-Cl, pH 8.0, and 2% Triton X-100. The column was washed with 5 volumes of the loading buffer, then 5 volumes of 0.6 M NaCl in the same buffer and the 10 activity was eluted with 0.5 M KSCN in the same buffer. Active fractions were assayed for the synthesis of acyl-ACP, as described below, combined, and bound to 3 mL settled-volume of hydroxlyapatite 15 equilibrated in 50 mM Tris-Cl, pH 8.0, 2% Triton X-100. The hydroxylapatite was collected by centrifugation, washed twice with 20 mL of 50 mM Tris-Cl, pH 8.0, 2% Triton X-100. The activity was eluted with two 5 mL washes of 0.5 M potassium phosphate, pH 7.5, 2% Triton X-100. The first wash 20 contained 66% of the activity and it was concentrated with a 30 kD membrane filtration concentrator (Amicon) to 1.5 mL.

Synthesis of Radiolabeled Acyl-ACP

A solutions of [14C] palmitic acid, [14C] stearic acid, [14C] oleic acid, [14C] lauric acid, and [14C] decanoic acid (120 nmoles each) prepared in methanol were dried in glass reaction vials. The ACP preparation described above (1.15 mL, 32 nmoles) was added along with 0.1 mL of 0.1 M ATP, 0.05 mL of 80 mM DTT, 0.1 mL of 8 M LiCl, and 0.2 mL of 13% Triton X-100 in 0.5 M Tris-Cl, pH 8.0, with 0.1 M MgCl₂. The reaction was mixed thoroughly and 0.3 mL of the acyl-ACP synthase preparation was added and the reaction was incubated at 37°C. After one-half h intervals a 10 µL aliquot was taken and dried on a small filter paper disc. The disc was washed extensively with chloroform:methanol:acetic acid (8:2:1, v:v:v) and

radioactively retained on the disc was aken as a measure of [14C]- acyl-ACP. At 2 h about 88% of the ACP had been consumed. The reaction mixes were diluted 1 to 4 with 20 mM Tris-Cl, pH 8.0, and applied to 1 mL DEAE-Sephacel columns equilibrated in the same buffer. The columns were washed in sequence with 5 mL of 20 mM Tris-Cl, pH 8.0, 5 mL of 80% 2-propanol in 20 mM Tris-Cl, pH 8.0, and eluted with 0.5 M LiCl in 20 mM Tris-Cl, pH 8.0. The column eluates were passed directly onto 3 mL columns of octyl-sepharose CL-4B which were washed with 10 mL of 20 mM potassium phosphate, pH 6.8, and then eluted with 35% 2-propanol in 2 mM potassium phosphate, pH 6.8. The eluted products were lyophilized and redissolved at a concentration of 24 µM.

EXAMPLE 1

ISOLATION OF CDNA'S FOR SOYBEAN AND CANOLA SEED PALMITOYL-ACP THIOESTERASE

PCR synthesis of a DNA probe for an Arabidopsis cDNA with sequence homology to a medium chain fatty acyl-ACP thioesterase

A portion of the sequence of an Arabidopsis cDNA sequenced in the Arabidopsis thaliana transcribed genome sequencing project (clone YAP140T7) obtained from Genbank entry Z17678 (Arabidopsis thaliana systematic cDNA sequencing reveals a gene with homology with Umbellularia californica C12:0-ACP thioesterase. (Francoise et al., Plant Physiol. Biochem. 31, 599, (1993)) and additional sequence from an Arabidopis thaliana cDNA clone obtained using that sequence and communicated by Dr. John Ohrolgge (Michigan State University) were used to make two PCR primers shown in SEQ ID NO:3 (the 5' extending primer) and SEQ ID NO:4 (the 3' extending primer). Total RNA was extracted from green seliques of Arabidopis plants and polysomal RNA was isolated following the procedure of Kamalay et al., (Cell (1980) 19:935-946). The polyadenylated mRNA fraction was obtained by affinity

chromatograph, on oligo-dT cellulose (Avivet al., Proc. Natl. Acad. Sci. USA (1972) 69:1408-1411). Thirteen ng of the polyadenylated mRNA was used as template for amplification from oligo-dT using a GeneAmp® RNA-PCR kit (Perkin Elmer Cetus, part number N808-0017). PCR was done at an annealing temperature of 52°C for 35 cycles. A DNA fragment of about 560 base pairs was generated and isolated by agarose gel purification.

The isolated fragment was used as the template for random primer labeling with [32p]dCTP.

Cloning of a Brassica napus Seed cDNA Homologus to the Arabidopis Thioesterase Like Fragment

The radiolabelled probe was used to screen a . 15 Brassica napus seed cDNA library. In order to construct the library, Brassica napus seeds were harvested 20-21 days after pollination, placed in liquid nitrogen, and polysomal RNA was isolated following the procedure of Kamalay et al., (Cell 20 (1980) 19:935-946). The polyadenylated mRNA fraction was obtained by affinity chromatography on oligo-dT cellulose (Aviv et al., supra). Four micrograms of this mRNA were used to construct a seed cDNA library in lambda phage (Uni-ZAP XR vector) using the protocol described in the ZAP-cDNA Synthesis Kit 25 (1991 Stratagene Catalog, Item #200400). Approximately 240,000 clones were screened for positively hybridizing plaques using the radiolabelled, PCR derived probe described above 30 essentially as described in Sambrook et al., supra except that low stringency hybridization conditions (50 mM Tris, pH 7.6, 6X SSC, 5X Denhardt's, 0.5% SDS, 100 µg denatured calf thymus DNA and 50°C) were used and post-hybridization washes were performed twice with 2X SSC, 0.5% SDS at room temperature for 15 min, 35 then twice with 0.2X SSC, 0.5% SDS at room temperature for 15 min, and then twice with 0.2X SSC, 0.5% SDS at 50°C for 15 min. Nine positive plaques showing strong

hybridization were picked, plated out, nd the screening procedure was repeated. From the secondary screen four, pure phage plaques were isolated. Plasmid clones containing the cDNA inserts were obtained through the use of a helper phage according to the in vivo excision protocol provided by Stratagene. Double-stranded DNA was prepared using the Magic® Miniprep (Promega) and the manufacturers instructions, and the resulting plasmids were sizeanalyzed by electrophoresis in agarose gels. One of 10 the four clones, designated p5a, contained an approximately 1.5 kb insert which was sequenced from both strands by the di-deoxy method. The sequence of 1483 bases of the cDNA insert of p5a is shown in SEQ ID NO:1. A second clone, designated p2a was also 15 sequenced and found to contain a 1673 base pair cDNA shown in SEQ ID NO:31. The sequences of the two cDNA inserts are 85% identical overall, they encode peptides that are 92% identical overall but which are 94% identical within the region of the putative mature 20 peptide (the peptide after removal of the plastid transit sequence). The cDNA regions of the two cDNAs which encode the mature peptides are 90.4% identical. The two cDNAs probably encode two isozymes of the same activity. Based on the length of the transit peptides 25 for the two sequences, the length of the respective cDNAs and alignments to the soybean sequences shown below, it appears that the cDNA in clone p5a is a slightly truncated version of the actual message while clone p2a represents a full length message. The cDNA 30 isolated from clone p2a has been sequenced and the sequence is given in SEQ ID NO 31. Cloning of a Soybean Seed cDNA Homologus to the

Arabidopis Thioesterase Like Fragment

35

A cDNA library was made as follows: Soybean embryos (ca. 50 mg fresh weight each) were removed from the pods and frozen in liquid nitrogen. The frozen embryos were ground to a fine powder in the

presence of 1 did nitrogen and then extra Polytron homogenization and fractionated to enrich for total RNA by the method of Chirgwin et al. (Biochemistry (1979) 18:5294-5299). The nucleic acid fraction was enriched for poly A+RNA by passing total 5 RNA through an oligo-dT cellulose column and eluting the poly A+RNA with salt as described by Goodman et al. (Meth. Enzymol. (1979) 68:75-90). cDNA was synthesized from the purified poly A+RNA using cDNA Synthesis System (Bethesda Research Laboratory) and 10 the manufacturer's instructions. The resultant double-stranded DNA was methylated by Eco RI DNA methylase (Promega) prior to filling-in its ends with T4 DNA polymerase (Bethesda Research Laboratory) and blunt-end ligation to phosphorylated Eco RI linkers 15 using T4 DNA ligase (Pharmacia, Upsalla Sweden). double-stranded DNA was digested with Eco RI enzyme, separated from excess linkers by passage through a gel filtration column (Sepharose CL-4B), and ligated to 20 lambda ZAP vector (Stratagene, 1109 N. Torrey Pine Rd., LaJolla CA.) according to manufacturer's instructions. Ligated DNA was packaged into phage using the Gigapack packaging extract (Stratagene) according to manufacturer's instructions. resultant cDNA library was amplified as per 25 Stratagene's instructions and stored at -80°C.

Following the instructions in the Lambda ZAP Cloning Kit Manual (Stratagene), the cDNA phage library was used to infect E. coli BB4 cells and a total of approximately 360,000 plaque forming units were plated onto 6, 150 mm diameter petri plates. Duplicate lifts of the plates were made onto nitrocellulose filters (Schleicher & Schuell). The filters were prehybridized in 25 mL of hybridization buffer consisting of 6X SSPE, 5X Denhardt's solution, 0.5% SDS, 5% dextran sulfate and 0.1 mg/mL denatured salmon sperm DNA (Sigma Chemical Co.) at 50°C for 2 h. Radiolabelled probe based on the Arabidopsis PCR

30

35

product decribed above was added, and allowed to hybridize for 18 h at 50°C. The filters were washed exactly as described above. Autoradiography of the filters indicated that there were 9 strongly hybridizing plaques. The 9 plaques were subjected to a second round of screening as before.

From the secondary screen three, pure phage plaques were isolated. Plasmid clones containing the cDNA inserts were obtained through the use of a helper phage according to the in vivo excision protocol 10 provided by Stratagene. Double-stranded DNA was prepared using the Magic® Miniprep (Promega) and the manufacturers instructions, and the resulting plasmids were size-analyzed by electrophoresis in agarose gels. One of the four clones, designated p233b, contained an 15 approximately 1.2 kb insert one strand of which was partially sequenced by the di-deoxy method. bases of p233b that were sequenced showed a sequence identity of 81.2% in comparison to the Arabidopsis thioesterase like sequence which was the basis for the 20 PCR probe. The other two clones isolated from the inital screening appeared to be cDNA concatomers in which the primary inserts were of a size similar to p233a. Comparison of the sequence at the 5 prime end of p233a to both the canola sequence and the 25 Arabidopsis sequence indicated that p233a is a 5 prime truncated version of the putative thioesterase. The cDNA insert of p233b was removed by digestion with Eco RI and the insert was purified by agarose gel electrophoresis. The purified insert was used as the 30 template for random primer labeling as described above. Approximately 150,000 plaque forming units of the soybean seed cDNA library were plated on three plates as described above and duplicate nitrocellulose lifts were screened at high stringency (hybridization 35 at 60°C in 6xSCC, 0.1% SDS for 18 hr, washing at 60°C in 0.2xSSC, 0.1% SDS twice for 10 min each). Of 18 positive plaques obtained, one designated pTE11, and

WO 96/06936

5

20

25

PCT/US95/10627

containing a so kB insert was chosen for equencing by the di-deoxy method. The sequence of the 1688 bases in the soybean cDNA insert of pTE11 are shown in SEO ID 2.

EXAMPLE 2

EXPRESSION OF THE CATALYTICALLY ACTIVE PROTEIN ENCODED BY THE SOYBEAN AND CANOLA CDNA'S HOMOLOGUS TO THE PUTATIVE THIOESTERASE FROM ARABIDOPSIS IN E. COLI

Plasmid vectors for the expression of the

portions of the soybean and canola putative
thioesterase cDNA's assumed to encode the pro-protein
were made using the vector pET-3d (described by F. W.
Studier, A. H. Rosenberg, J. J. Dunn and J. W.
Dubendorff, Methods in Enzymology Vol. 185) and the

host cell strain BL21(DE3) (pLysE).

The canola clone p5a was digested with Pvu II and Hin DIII to release a 1235 base pair fragment which was blunted with DNA polymerase I before isolation by agarose gel electrophoresis. Two oligonucletides were synthesisized which, when annealed together form the following linker sequence:

5'-CATGGAGGAGCAG (SEQ ID NO:3) 3'-CTCCTCGTC (SEQ ID NO:4)

The linkers were ligated to the 1235 base pair fragment which was then ligated into the Nco I digested and calf intestinal phosphatase treated The ligation mixture was used to transform competent BL21 (DE3) (pLyE) cells and twenty ampicillin 30 resistant clonies were used to inocculate 5 mL liquid cultures. Plasmid DNA was prepared from the cultures and digested with Pvu II, Nco I and Eco RI to determine the presence of an insert and its orientation with respect to the T7 promoter. Only one 35 insert containing plasmid was obtained, and the orientation of the conding region with respect to the promoter was reversed. The plasmid DNA was digested with Nco I, the insert isolated and religated into

Nco I digented, phosphatase treated pends as above. The ligation mixture was used to transform competent XL-1 cells. Ten isolated colonies were used to inocculate 5 mL liquid cultures and plasmid DNA was isolated. Three clones were determined to be in the forward direction by their Eco RI restriction fragment pattern. The region across the cloning site was sequenced and found to place the start methionine encoded by the linker DNA sequence in frame with the protein encoded by the canola cDNA to give the deduce amino acid sequence shown in SEQ ID NO:6.

10

15

20

25

30

35

The soybean cDNA containing plamid pTE11 was digested with Sph I and Eco RI, blunted with DNA polymerase I and the resulting 1208 base pair fragment was isolated by agarose gel electrophoresis. above described linkers were ligated to the fragment and the product was ligated into the pET-3b vector as described for the canola cDNA fragment above. ligation mixture was used to transform competent XL-1 cells and ten of the colonies obtained were used to inocculate 5 mL liquid cultures. Plasmid DNA isolated from the cultures was digested with Nco I to determine the presence of a cDNA insert and with Hpa I and Sph I to determine the orientation of the insert relative to the T7 promoter. One clone with a correctly oriented insert was obtained and used to transform competent BL21 (DE3) (pLysE) cells. The deduced amino acid sequence of the expressed protein is shown in SEQ ID NO:7.

Single colonies of the BL21(DE3)(pLysE) strains containing the pET: canola and the soybean cDNA expression vectors were used to inocculate 5 mL of 2xYT media containing 50 mg/L ampicillin. The cultures were grown overnight at 37°C, diluted to 0.1 OD at 600 nm with fresh, ampicillin containing media and re-grown to 1.5 OD at 600 nm at 37°C. Both cultures were induced by the addition of IPTG to a final concentration of 1 mM. Cells were harvested by

10

15

centrifugation. Three hr after induction. Prolume of lysis buffer (50 mM HEPES, pH 7.5, 15 mM NaCl, 0.5 mM EDTA, 1 mM DTT and 15% glycerol; approximately equal to the pellet volume was added and the cells were resuspended by vortex mixing. A small amount of 2 mm glass beads and 0.2 M PMSF in 2-propanol to a final concentration of 0.2 mM was added just before sonication. The cell lysate was centrifuged in a microfuge to clear and the supernatent of the canola cDNA expressing cell line was diluted one to twenty with 50 mM Tricine (pH 8.2, 1 mg/mL BSA and 1 mM DTT) to give a lysate protein concentration of 1.8 mg/mL. The cell line expressing the soybean cDNA was similarly diluted one to five to give a lysate protein concentration of 2.4 mg/mL.

Acyl-ACP thioesterase assay

Reagents and substrates for the thioesterase assay are prepared as described above in the the MATERIALS AND METHODS section. Acyl-ACP thioesterase 20 was assayed as described by Mckeon and Stumpf [J. Biol. Chem. (1982) 257:12141-12147]. Each of the radiolabeled acyl-ACP's were adjusted to concentrations ranging from 0.18 µM to 2.06 µM and a volume of 40 µL with a reaction buffer consisting of 25 1 mg/mL bovine serum albumin in CAPS-NaOH buffer (50 mM) at pH 9.5. Reactions were started with lysate from E. coli expressing the plant cDNA's for the putative acyl-ACP thioesterase from either soybean seed or canola seed and incubated for times varying from 12 seconds to 1 min depending upon the activity of the fraction. Reactions were terminated by the addition of 100 µl of a solution of 5% acetic acid in 2-propanol and extracted twice with 1 mL each of water saturated hexane. Five mL of ScintiVerse Bio HP (Fisher) scintillation fluid was added to the combined 35 extracts and radioactivity in the released fatty acids was determined by scintilation counting.

Thiose erase assays done on E. collectracts from cultures which were not transformed with thioesterase expressing plasmids had specific activities of about 0.025 nmole/min/mg protein in the palmitoyl-ACP, stearoyl-ACP and oleoyl-ACP assays when the assay was done at 1 µM substrate concentration. Since this E. coli background was from 70 to 150 fold less than the activity found in the plant thioesterase expressing lines, it is ignored in the following data.

Assays were done at 4 substrate concentrations for the soybean enzyme and at a concentration which gave maximal activity for the canola enzyme. Assays were done such that less than 25% of the available substrate was consumed at each substrate concentration and the substrate concentration listed in Table 2 is the average concentration during the time of the reaction.

*Data from a seperate experiment in which the pET:soybean palmitoly thioesterase was expressed to a higher level in BL21(DE3) cells.

The data in Table 2 shows that both the canola and the soybean enzymes are acyl-ACP thioesterases. While neither enzyme has significant activity toward lauroyl-ACP or decanoly-ACP which is the substrate for the enzyme that they were initially idenified as homologus to (Arabidopsis thaliana systematic cDNA sequencing reveals a gene with homology with Umbellularia californica C12:0-ACP thioesterase.

- 10 Francoise Grellet, Richard Cooke, Monique Raynal, Michele Laudie and Michel Delseny, Plant Physiol. Biochem. 1993 31:599-602), both are active against longer acyl chain-ACP's. Both have a preference of between two and three fold for palmitoyl-ACP over
- either stearoyl-ACP or oleoyl-ACP. This is in contrast to the known acyl-ACP thioesterases from these species which show a strong substrate preference for oleoyl-ACP [WO 9211373]. The enzymes thus represent a second class of acyl-ACP thioesterase,
- present within the same tissues as the oleoyl-ACP thioesterase which have substrate preference for long chain, saturated acyl-ACP's.

EXAMPLE 3

REGULATION OF THE EXPRESSION OF PALMITOYL-ACP THIOESTERASE IN SOYBEANS

Construction of Vectors for Transformation of Glycine
max for Reduced Expression of Palmitoyl-ACP
thioesterase in Developing Soybean Seeds

plasmids containing the antisense *G. max*palmitoyl-ACP thioesterase cDNA sequence under control
of the soybean beta-conglycinin promoter (Beachy
et al., EMBO J. (1985) 4:3047-3053), were constructed.
The construction of vectors expressing the soybean
delta-12 desaturase antisense cDNA under the control
of these promoters was facilitated by the use of
plasmids pCW109 and pML18, both of which are described
in [WO 9411516].

A unique Not I site was introduced into the cloning region between the beta-conglicinin promoter and the phaseolin 3' end in pCW109 by digestion with Nco I and Xba I followed by removal of the single stranded DNA ends with mung bean exonuclease. Not I linkers (New England Biochemical catalog number NEB 1125) were ligated into the linearized plasmid to produce plasmid pAW35. The single Not I site in pML18 was destroyed by digestion with Not I, filling in the single stranded ends with dNTP's and Klenow fragment followed by re-ligation of the linearized plasmid. The modified pML18 was then digested with Hind III and treated with calf intestinal phosphatase.

The beta-conglicinin:Not I:phaseolin expression cassette in pAW35 was removed by digestion with Hind III and the 1.79 kB fragment was isolated by agarose gel electrophoresis. The isolated fragment was ligated into the modified and linearized pML18 construction described above. A clone with the desired orientation was identified by digestion with Not I and Xba I to release a 1.08 kB fragment indicating that the orientation of the betaconglycinin transcription unit was the same as the

selectable maker transcription unit. The esulting plasmid was given the name pBS19.

PCR amplification primers SOYTE3

(5'-AAGGAAAAAAGCGGCCGCTGACACAATAGCCCTTCT-3') (SEQ ID NO:5) corresponding to bases 1 to 16 of SEQ ID NO:1 with additional bases to provide a Not I restriction site and sufficient additional bases to allow Not I digestion and SOYTE4

(5'-AAGGAAAAAGCGGCCGCGATTTACTGCTGCTTTTC-3') (SEQ ID NO:12) corresponding to the reverse complement of bases 1640 to 1657 of SEQ ID NO:1 with additional bases to provide a Not I restriction site and sufficient additional bases to allow Not I digestion were synthesiszed. Using these primers, pTE11 as

template and standard PCR amplification procedures (Perkin Elmer Cetus, GeneAmp PCR kit), a 1.6 kB fragment of p233b was amplified and isolated by agarose gel electrophoresis. The fragment was digested overnight at 37° with Not I, extracted with

phenol/chloroform followed by chloroform extraction and ethanol precipitation. Plasmid pBS19 was digested with Not I, treated with calf intestinal phosphatase and the linearized plasmid was purified by agarose gel electrophoresis. The Not I digested, PCR amplified

fragment of pTE11 described above was ligated into the linearized pBS19 and the ligation mixture used to transform competent X1-1 cells. A clone in which the soybean palmitoyl-ACP cDNA was oriented in the antisense direction with respect to the beta-

30 conglycinin promoter was identified by digestion with Hind III. The antisense orientation releases fragments of 1.6 and 1.9 kB while the sense orientation releases fragments of 1.15 and 2.3 kB. The antisense soybean palmitoyl-ACP thioesterase

plasmid was designated pTC3 and the sense oriented plasmid was designated pTC4.

Transforma on Of Somatic Soybean Embr Cultures

Soybean embryogenic suspension cultures were maintained in 35 mL liquid media (SB55 or SBP6, MATERIALS AND METHODS) on a rotary shaker, 150 rpm, at 28°C with mixed fluorescent and incandescent lights on a 16:8 h day/night schedule. Cultures were subcultured every four weeks by inoculating approximately 35 mg of tissue into 35 mL of liquid medium.

5

10

15

20

25

30

35

Soybean embryogenic suspension cultures were transformed with pTC3 by the method of particle gun bombardment (see Kline et al. (1987) Nature (London) 327:70). A DuPont Biolistic PDS1000/HE instrument (helium retrofit) was used for these transformations.

To 50 mL of a 60 mg/mL 1 mm gold particle suspension was added (in order); 5 uL DNA(1 ug/uL), 20 uL spermidine (0.1 M), and 50 uL CaCl₂ (2.5 M). The particle preparation was agitated for 3 min, spun in a microfuge for 10 sec and the supernatant removed. The DNA-coated particles were then washed once in 400 uL 70% ethanol and are suspended in 40 uL of anhydrous ethanol. The DNA/particle suspension was sonicated three times for 1 sec each. Five uL of the DNA-coated gold particles were then loaded on each macro carrier disk.

Approximately 300-400 mg of a four week old suspension culture was placed in an empty 60x15 mm petri dish and the residual liquid removed from the tissue with a pipette. For each transformation experiment, approximately 5-10 plates of tissue were normally bombarded. Membrane rupture pressure was set at 1000 psi and the chamber was evacuated to a vacuum of 28 inches of mercury. The tissue was placed approximately 3.5 inches away from the retaining screen and bombarded three times. Following bombardment, the tissue was placed back into liquid and cultured as described above.

WO 96/06936

15

20

25

30

35

Eleven de post bombardment, the lique media was exchanged with fresh SB55 containing 50 mg/mL hygromycin. The selective media was refreshed weekly. Seven weeks post bombardment, green, transformed tissue was observed growing from untransformed, necrotic embryogenic clusters. Isolated green tissue was removed and inoculated into individual flasks to generate new, clonally propagated, transformed embryogenic suspension cultures. Thus each new line was treated as independent transformation event. These suspensions can then be maintained as suspensions of embryos clustered in an immature developmental stage through subculture or regenerated into whole plants by maturation and germination of individual somatic embryos.

Transformed embryogenic clusters were removed from liquid culture and placed on a solid agar media (SB103, MATERIALS AND METHODS) containing no hormones or antibiotics. Embryos were cultured for four weeks at 26°C with mixed fluorescent and incandescent lights on a 16:8 h day/night schedule before analysis.

Analysis Of Transgenic Glycine Max Embryos Containing An Antisense Palmitoyl-ACP Thioesterase Construct

The vector pTC3 containing the soybean palmitoyl-ACP thioesterase cDNA, in the antisense orientation, under the control of the soybean beta-conglycinin promoter as described above gave rise to seven mature embryo lines. A culture of the embryo line used for transformation was carried through culture to mature embryos without transformation or selection to serve as a fatty acid profile control line. Fatty acid analysis was performed by gas chromatography of the fatty acyl methyl esters essentially as described by Browse et al., (Anal. Biochem. (1986) 152:141-145) except that 2.5% H₂SO₄ in methanol was used as the methylation reagent and samples were heated for 1.5 h at 80°C to effect the methanolysis of the embryo lipids using single, mature embryos as the tissue

source. The to ten embryos from eac. Transformed line and 5 embryos from the untransformed control were analyzed and the results are shown in Table 3.

The average palmitate content of six of the seven transformed lines is significantly less than that of the control embryo line. In each of these six lines, the average stearate content is also less than the control average. This result is expected if the palmitoyl-ACP thioesterase is responsible for the release of all or part of the palmitate that is incorporated into triacylglyceride and if the antisense construction has reduced the amount of palmitoyl-ACP thioesterase produced. Since the 10 stearate content of the lines is decreased rather than increased in correspondence with the decreased palmitate, the following may be inferred: capacity to elongate palmitoyl-ACP to stearoyl-ACP 15 must be sufficient to convert the increased flux to stearate, and the capacity to desaturate stearoyl-ACP to oleoly-ACP must also be sufficient to convert the increased flux to oleate. These two events lead to a significant decrease in the total saturated fatty acids produced in the transformed embryos. 20 also be inferred that the oleate desaturating capacity is present in excess of the substrate supplied to it since most of the carbon which was not removed from the ACP synthetic track is found in the linoleate 25 fraction.

WO 96/06936

This is no most clearly in a companion of lines 357/1/3 and 357/5/1. Line 357/1/3 was transformed but shows little or no alteration in fatty acid phenotype while line 357/5/1 is quite uniform among all tested embryos in producing an altered fatty acid phenotype. The average palmitic acid content of the lipid in line 357/5/1 is 3.2 fold less than that of line 357/1/3 and the average stearic acid content of 357/1/3 is 1.8 fold less than that of line 357/5/1.

The combined saturated fatty acid decrease is 12.2% of the total fatty acid, and of that 12.2%, nearly all (11.7%) can be accounted for as increased oleate and linoleate.

Thus, the combined effect is a soybean embryo line with 65% less saturated fatty acid and with increased monounsaturated and polyunsaturated fatty acid.

From this data we conclude that reduction of the amount of palmitoyl-ACP thioesterase expressed in developing soybean seeds will lead to the production of soybean oil with reduced saturated fatty acid content. The variation in the amount of antisense effect observed between embryos but within a transformed line seen in Table 3 is a characteristic of this transformation system which is explained more fully below. The relation between data taken from the immature embryos and seeds from the zygotic embryos produced on plants regenerated from these somatic embryos is dicussed below.

The Fatty Acid Phenotype Resulting From Antisense Or Co-Suppression Inhibition Of Gene Expression In Soybean Somatic Embryos Is Predictive Of The Fatty Acid Phenotype Of Seeds Of Plants Regenerated From Those Embryos

Mature somatic soybean embryos are a good model for zygotic embryos. While in the globular embryo state in liquid culture, somatic soybean embryos contain very low amounts of triacylglycerol or storage

proteins pical of maturing, zygoti ovbean embryos. At this developmental stage, the ratio of total triacylglyceride to total polar lipid (phospholipids and glycolipid) is about 1:4, as is typical of zygotic soybean embryos at the developmental stage from which the somatic embryo culture was initiated. At the globular stage as well, the mRNAs for the prominent seed proteins, alpha' subunit of beta-conglycinin, kunitz trypsin inhibitor 3, and seed lectin are essentially absent. 10 transfer to hormone-free media to allow differentiation to the maturing somatic embryo state, triacylglycerol becomes the most abundant lipid class. As well, mRNAs for alpha'-subunit of beta-conglycinin, kunitz trypsin inhibitor 3 and seed lectin become very 15 abundant messages in the total mRNA population. On this basis the somatic soybean embryo system behaves very similarly to maturing zygotic soybean embryos in vivo, and is therefore a good and rapid model system for analyzing the phenotypic effects of modifying the 20 expression of genes in the fatty acid biosynthesis pathway.

Most importantly, the model system is also predictive of the fatty acid composition of seeds from plants derived from transgenic embryos. This is illustrated with two different antisense constructs in two different types of experiment and in a similar cosuppression experiment:

25

Liquid culture globular embryos transformed with

a chimeric gene consisting of soybean microsomal
delta-15 desaturase (experiment 1, WO 9311245) or
soybean microsomal delta-12 desaturase (experiment 2)
in antisense orientation under the control of a seedspecific promoter (beta-conglycinin promoter) gave

rise to mature embryos. The fatty acid content of
mature somatic embryos from lines transformed with
vector only (control) and the vector containing the
antisense chimeric genes as well as of seeds of plants

regenerated the them was determined. In experiment 1, one set of embryos from each line was analyzed for fatty acid content and another set of embryos from that same line was regenerated into

5 plants. In experiment 2, different lines, containing the same antisense construct, were used for fatty acid analysis in somatic embryos and for regeneration into plants. In experiment 1, in all cases where a reduced 18:3 content was seen in a transgenic embryo line,

10 compared with the control, a reduced 18:3 content was also observed in segregating seeds of plants derived from that line, when compared with the control seed (Table 4).

In experiment 2, about 55% of the transformed embryo lines showed an increased 18:1 content when 15 compared with control lines (Table 5). Soybean seeds, of plants regenerated from different somatic embryo lines containing the same antisense construct, had a similar frequency (53%) of high oleate transformants as the somatic embryos (Table 5). On occasion, an 20 embryo line may be chimeric. That is, 10-70% of the embroys in a line may not contain the transgene. remaining embryos which do contain the transgene, have been found in all cases to be clonal. In such a case, 25 plants with both wild type and transgenic phenotypes may be regenerated from a single, transgenic line, even if most of the embryos analyzed from that line had a transgenic phenotype. An example of this is shown in Table 6 in which, of 5 plants regenerated 30 from a single embryo line, 3 have a high oleic phenotype and two were wild type. In most cases, all the plants regenerated from a single transgenic line will have seeds containing the transgene.

Transformant Line	Embyro average (SD n=10)	Seed average* (SD. n=10)
Control	12.1 (2.6)	8.9 (0.8)
Δ 15 antisense, line 1	5.6 (1.2)	4.3 (1.6)
Δ 15 antisense, line 2	8.9 (2.2)	2.5 (1.8)
Δ 15 antisense, line 3	7.3 (1.1)	4.9 (1.9)
Δ 15 antisense, line 4	7.0 (1.9)	2.4 (1.7)
Δ 15 antisense, line 5	8.5 (1.9)	4.5 (2.2)
Δ 15 antisense, line 6	7.6 (1.6)	4.6 (1.6)

^{*[}Seeds which were segregating with wild-type phenotype and without a copy of the transgene are not included in these averages]

TABLE 5
Oleate Levels in Somatic Embryos And Seeds Of
Regenerated Soybeans Transformed With or Without
Delta-12 Desaturase Antisense Construct

Vector	# of lines	<pre># of lines with high 18:1</pre>	Average# <u>%18:1</u>
Somatic embryos:			
Control	19	0	12.0
D 12 antisense	20	11	35.3
Seeds of regener	ated plants:		
Control	6	0	18.2
D 12 antisense	17	/9	44.4

^{*}average 18:1 of transgenics is the average of all embryos or seeds transformed with the delta-12 antisense construct in which at least one embryo or seed from that line had an 18:1 content greater than 2 standard deviations from the control value (12.0 in embryos, 18.2 in seeds). The control average is the average of embryos or seeds which do not contain any transgenic DNA but have been treated in an identical manner to the transgenics

Mean of 15-20 seeds from 5 different plants regenerated from a single embryo line. Only plants # 2, 9 and 11 have seeds with a high 18:1 phenotype

Line 4 Plant #	Average seed 18:1 %	Highest seed 18:1 %
1	18.0	26.3
2	33.6	72.1
7	13.6	21.2
9	32.9	57.3
11	24.5	41.7

In a similar experiment, 75% of the coding region (begining at the 5' end) of the delta-12 desaturase sequence and of the delta-15 desaturase sequence were each placed behind the b-conglycinin promoter in a single construction for soybean transformation as described above. As in experiment 2 above, seperate embryo sets were used for analysis at the embryo stage and regeneration into fertile plants. The average 18:1 and 18:3 content in five embryos from each of 7 transformed lines is given in Table 7. Of the 7 lines 10 two clearly have elevated levels of 18:1 as would be expected of embryos in which the conversion of 18:1 to 18:2 by delta-12 desaturase is limited due to decreased expression of the enzyme. In these same lines there is a slight decrease in the 18:3 content, 15 indicative of a decreased delta-15 desaturase activity.

TABLE 7

The 18:1 and 18:3 content in somatic embryos from seven lines transfromed with a combined Delta-12 and Delta-15 co-suppression construct.

Values are	the mean of five individ	ual embryos
Line	\$18:1	318:3
561/1/1	45.1	10.1
561/1/2	18.4	13.8
561/1/3	10.7	15.2
561/4/1	39.3	13.4
561/4/2	18.7	13.2

561,	19.7	14.1
561/4/5	14.6	16.1
561/4/6	43.9	12.9

Twenty, fertile soybean plants were regenerated from somatic embryos transformed with the combined D12/D15 desaturase co-suppression construction described above. Five single seeds from each plant 5 were analyzed and of the twenty lines, two showed bulk fatty acid profiles which suggested that both the D 12 and D 15 desaturase activities were decreased. first seeds from transformed plants should be genetically segregating for the transgene so single 10 seeds from these two lines were analyzed to derive an estimate of the number of transgene loci contributitng to the fatty acid phenotype. Ninty nine seeds of line 557-2-8-1 were analyzed and 137 seeds of line 557-2-8-2 were analyzed. The fatty acid profile 15 classes from both lines were consistent with two transgenic loci contributing to the phenotype. The average fatty acid profile of the seeds which were judged to be in the high segregant class are given in Table 8 for both of these lines. 20

Table 8

The average fatty acid profiles (as % of total fatty acids) for the probable double homozygous seeds from two lines segregating for co-suppression

25 transgenes for the Δ 12 and Δ 15 desaturases. The data are the mean of 10 single seed profiles for line 557-2-8-1 and 13 single seed profiles for line 557-2-8-2. The profile from a non-transformed line grown along with the transformed lines in shown for comparison.

Line	16:0	18:0	18:1	18:2	18:3
557-2-8-1	8.6	2.1	82.5	2.5	4.2
557-2-8-2	8.3	2.1	82.0	2.2	5.0
non-transformed	13.3	2.4	17.4	52.3	19.2

WO 96/06936

As with the antisense constructions, and fatty acid profiles observed in the somatic embryos is predictive of the type and magnitude of alteration in fatty acid profile which will be obtained from the seeds of fertile plants transformed with the same construction as the somatic embryos. Thus, we conclude that an altered fatty acid phenotype observed in a transgenic, mature somatic embryo line is predictive of an altered fatty acid composition of seeds of plants derived from that line.

Analysis Of Transgenic Glycine Max Embryos Containing A Palmitoyl-ACP Thioesterase Construct In The Sense Orientation

The vector pTC4 contains the soybean palmitoyl
15 ACP thioesterase cDNA, in the sense orientation, under
the control of the soybean beta-conglycinin promoter
as described above gave rise to six mature embryo
lines in the soybean somatic embryo system. From 6 to
10 embryos from each of these lines were analyzed for
20 relative content of each fatty acid as described
above. The results are shown in Table 9.

TABLE 9

361/5/2	10	26.6	3.7	9.8	44.9	14.0

As is often the case when increasing the expression of an mRNA which is endogenous to the targeted tissue, the effects of both over-expression of the resulting enzyme and under expresssion of the enzyme due to co-supression are seen in this experiment. While lines 361/1/1 and 361/2/1 have fatty acid profiles very similar to control lines (shown in Table 9), most of the embryos in line 361/1/2 have levels of palmitic acid which are about 3 10 fold lower than controls or transformed lines which do not show altered fatty acid phenotype. In contrast, the palmitic acid content of all of the embryos in line 361/5/2 is increased and the average palmitic acid content is 26.2% or 1.8 times the average control 15 embryo. Line 361/2/2 contains 8 embryos which show the co-supression phenotype (low palmitic acid) and one embryo which shows the over expression phenotype (high palmitic acid content).

In this experiment the effects of altered
expression of the soybean palmitoyl-ACP thioesterase
are seen in both directions, and the resulting
phenotypes are as expected from the substrate
specificity of the enzyme. Modulation of expression
upward increases the relative palmitic acid content
and downward decreases the relative palmitic acid
content.

EXAMPLE 4

REGULATION OF EXPRESSION OF

PALMITOYL-ACP THIOESTERASE IN CANOLA

Construction Of Vectors For Transformation Of Brassica
Napus For Reduced Expression Of Palmitoyl-ACP
thioesterase In Developing Canola Seeds

An extended poly A tail was removed from the canola palmitoyl-ACP thioesterase sequence contained in plasmid p5b as follows. Plasmid p5b was digested with Eco RI and Ssp I and the 1.5 kB fragment released from the pBluescript vector was isolated by agarose gel electrophoresis. The single stranded ends were filled in with Klenow fragment and dNTP's.

Canola napin promoter expression cassettes were constructed as follows: Eight oligonucleotide primers were synthesized based upon the nucleotide sequence of napin lambda clone CGN1-2 published in European Patent 255 378. The oligonucleotide sequences were:

		·	
	BR42:	5'-AACATCAATGGCAGCAACTGCGGA-3'	13
20	BR43:	5'-GCCGGCTGGATTTGTGGCATCAT-3'	14
	BR45:	5'-CTAGATCTCCATGGGTGTATGTTCTGTAGTGATG-3'	15
	BR46:	5'-TCAGGCCTGTCGACCTGCGGATCAAGCAGCTTTCA-3'	16
	BR47:	5'-CTAGATCTGGTACCTAGATTCCAAACGAAIATCCT-3'	17
	BR48:	5'-AACATCAGGCAAGTTAGCATTTGC-3'	18
25	BR49:	5'-TCAGGCCTGTCGACGAGGTCCTTCGTCAGCATAT-3'	19
	BR50:	5'-AACGAACCAATGACTTCACTGGGA-3'	20
	Genomi	DNA from the canola variety 'Hyola401' (Zeneo	:a
	Seeds)	was used as a template for PCR amplification of)f
	the nap	oin promoter and napin terminator regions. The	:
30	promote	er was first amplified using primers BR42 and	
	BR43, a	and reamplified using primers BR45 and BR46.	
	Plasmid	plMC01 was derived by digestion of the 1.0 kb)
	promote	er PCR product with Sall/Bglll and ligation int	0
	Sall/Ba	mHI digested pBluescript SK+ (Stratagene). Th	.e
35	napin t	erminator region was amplified using primers	
	BR48 an	d BR50, and reamplified using primers BR47 and	
	BR49.	Plasmid plMC06 was derived by digestion of the	
	1.2 kb	terminator PCR product with Sall/Bglll and	

ligation into 11/Bglll digested pSP72 (A mega). Using plMC06 as a template, the terminator region was reamplified by PCR using primer

5 BR57 5'-CCATGGGAGCTCGTCGACGAGGTCCTTCGTCACGAT-3' 21

and primer

BR58 5'-GAGCTCCCATGGAGATCTGGTACCTAGATTCCAAAC-3' 22

10

15

20

35

Plasmid plMC101 containing both the napin promoter and terminator was generated by digestion of the PCR product with Sacl/Ncol and ligation into Sacl/Ncol digested plMC01. Plasmid plMC101 contains a 2.2 kb napin expression cassette including complete napin 5' and 3' non-translated sequences and an introduced Ncol site at the translation start ATG. Primer BR61 5'-GACTATGTTCTGAATTCTCA-3' 23 and primer BR62 5'-GACAAGATCTGCGGCCGCTAAAGAGTGAAGCCGAGGCTC-3' 24 were used to PCR amplify an ~270 bp fragment from the 3' end of the napin promoter. Plasmid plMC401 was obtained by digestion of the resultant PCR product

obtained by digestion of the resultant PCR product with EcoRI/Bglll and ligation into EcoRI/Bglll digested plMC 1 01. Plasmid plMC40 1 contains a 2.2 kb napin expression cassette lacking the napin 5'

non-translated sequence and includes a Notl site at the transcription start.

The oligonucleotide sequences were:

BR42 and BR43 corresponding to bases 29 to 52 (BR42) and the complement of bases 1146 to 1169 (BR43) of SEQ ID NO:8.

BR45 and BR46 corresponding to bases 46 to 66 (BR46) and the complement of bases 1028 to 1047 (BR45) of SEQ ID NO:8. In addition BR46 had bases corresponding to a Sal I site (5'-GTCGAC-3') and a few additional bases (5'-TCAGGCCT-3') at its 5' end and BR45 had bases corresponding to a Bgl II

5

20

sit 5'-AGATCT-3') and two (5' 3') additional bases at the 5' end of the primer.

- BR47 and BR48 corresponding to bases 81 to 102 (BR47) and bases 22 to 45 (BR48) of SEQ ID NO:10. In addition, BR47 had two (5'-CT-3') additional bases at the 5' end of the primer followed by bases corresponding to a Bgl II site (5'-AGATCT-3') followed by a few additional bases (5'-TCAGGCCT-3'),
- 10 BR49 and BR50 corresponding to the complement of bases 1256 to 1275 (BR49) and the complement of bases 1274 to 1297 (BR50) of SEQ ID NO:10. In addition BR49 had bases corresponding to a Sal I site (5'-GTCGAC-3') and a few additional bases (5'-TCAGGCCT-3') at its 5' end.
 - BR57 and BR58 corresponding to the complement of bases 1258 to 1275 (BR57) and bases 81 to 93 (BR58) of SEQ ID NO:10. In addition the 5' end of BR57 had some extra bases (5'-CCATGG-3') followed by bases corresponding to a Sac I site (5'-GAGCTC-3') followed by more additional bases
 - (5'-GTCGACGAGG-3') (SEQ ID NO:25). The 5' end of BR58 had additional bases (5'-GAGCTC-3') followed by bases corresponding to a Nco I site
- 25 (5'-CCATGG-3') followed by additional bases (5' AGATCTGGTACC-3') (SEQ ID NO:26).
- BR61 and BR62 corresponding to bases 745 to 764 (BR61) and bases 993 to 1013 (BR62) of SEQ ID NO:8. In addition the 5' end of BR 62 had additional bases (5'-GACA-3') followed by bases corresponding to a Bgl II site (5'-AGATCT-3') followed by a few additional bases (5'-GCGGCCGC-3').

Genomic DNA from the canola variety 'Hyola401'

(Zeneca Seeds) was used as a template for PCR

amplification of the napin promoter and napin
terminator regions. The promoter was first amplified
using primers BR42 and BR43, and reamplified using
primers BR45 and BR46. Plasmid pIMC01 was derived by

30

35

digestion of the 1.0 kb promoter PCR product with SalI/BglII and ligation into SalI/BamHI digested pBluescript SK+ (Stratagene). The napin terminator region was amplified using primers BR48 and BR50, and reamplified using primers BR47 and BR49. Plasmid pIMC06 was derived by digestion of the 1.2 kb terminator PCR product with SalI/BglII and ligation into SalI/BglII digested pSP72 (Promega). Using pIMC06 as a template, the terminator region was reamplified by PCR using primer BR57 and primer BR58. 10 Plasmid pIMC101 containing both the napin promoter and terminator was generated by digestion of the PCR product with SacI/NcoI and ligation into SacI/NcoI digested pIMC01. Plasmid pIMC101 contains a 2.2 kb napin expression cassette including complete napin 5' 15 and 3' non-translated sequences and an introduced NcoI site at the translation start ATG. Primer BR61 and primer BR62 were used to PCR amplify an ~270 bp fragment from the 3' end of the napin promoter. Plasmid pIMC401 was obtained by digestion of the 20 resultant PCR product with EcoRI/BglII and ligation into EcoRI/BqlII digested pIMC101. Plasmid pIMC401 contains a 2.2 kb napin expression cassette lacking the napin 5' non-translated sequence and includes a NotI site at the transcription start. 25

Plasmid pIMC401 was digested with Not I and the single stranded ends filled with dNTP's and Klenow fragment. The linearized plasmid was treated with calf intestinal phosphatase. The phospatase treated and linearized plasmid was ligated to the blunted, 1.5 kB fragment of canola palmitoyl-ACP thioesterase described above. Transformation of competent E. colicells with the ligation mixture resulted in the isolation of clones in which the plant cDNA sequence was in the sense orientation with respect to the napin promoter (pIMC29) and in the antisense orientation (pIMC30).

ctor for transformation of e antisense palmitoyl-ACP thioesterase construction under control of the napin promoter into plants using Agrobacterium tumefaciens was produced by constructing a binary Ti plasmid vector system (Bevan, (1984) Nucl. Acids Res. 12:8711-8720). One starting vector for the system, (pZS199) is based on a vector which contains: (1) the chimeric gene nopaline synthase/neomycin phosphotransferase as a selectable marker for transformed plant cells (Brevan et al. (1984) Nature 304:184-186), 10 (2) the left and right borders of the T-DNA of the Ti plasmid (Brevan et al. (1984) Nucl. Acids Res. 12:8711-8720), (3) the E. coli lacZ α -complementing segment (Vieria and Messing (1982) Gene 19:259-267) with unique restriction endonuclease sites for Eco RI. 15 Kpn I, Bam HI, and Sal I, (4) the bacterial replication origin from the Pseudomonas plasmid pVS1 (Itoh et al. (1984) Plasmid 11:206-220), and (5) the bacterial neomycin phosphotransferase gene from Tn5 20 (Berg et al. (1975) Proc. Natnl. Acad. Sci. U.S.A. 72:3628-3632) as a selectable marker for transformed A. tumefaciens. The nopaline synthase promoter in the plant selectable marker was replaced by the 35S promoter (Odell et al. (1985) Nature, 313:810-813) by a standard restriction endonuclease digestion and 25 ligation strategy. The 35S promoter is required for efficient Brassica napus transformation as described below.

The binary vectors containing the sense and antisense palmitoyl-ACP thioesterase expression cassettes were constructed by digesting pIMC29 and pIMC30 with Sal I to release the napin:palmitoyl-ACP thioesterase cDNA:napin 3' sequence and agarose gel purification of the 3.8 kB fragments. Plasmid pZS199 was also digested with Sal I and the 3.8 kB fragments isolated from pIMC29 and pIMC30 were ligated into the linearized vector. Transformation and isolation of clones resulted in the binary vector containing the

30

35

30

sense construct (pIMC129) and the antisen construct (pIMC130).

Agrobacterium-Mediated Transformation Of Brassica
Napus

The binary vectors pIMC129 and pIMC130 were transferred by a freeze/thaw method (Holsters et al. (1978) Mol. Gen. Genet. 163:181-187) to the Agrobacterium strain LBA4404/pAL4404 (Hockema et al. (1983), Nature 303:179-180).

Brassica napus cultivar "Westar" was transformed by co-cultivation of seedling pieces with disarmed Agrobacterium tumefaciens strain LBA4404 carrying the the appropriate binary vector.

B. napus seeds were sterilized by stirring in 10% Chlorox, 0.1% SDS for thirty min, and then rinsed thoroughly with sterile distilled water. The seeds were germinated on sterile medium containing 30 mM CaCl₂ and 1.5% agar, and grown for six days in the dark at 24°C.

Liquid cultures of Agrobacterium for plant transformation were grown overnight at 28°C in Minimal A medium containing 100 mg/L kanamycin. The bacterial cells were pelleted by centrifugation and resuspended at a concentration of 10⁸ cells/mL in liquid Murashige and Skoog Minimal Organic medium containing 100 μM acetosyringone.

B. napus seedling hypocotyls were cut into 5 mm segments which were immediately placed into the bacterial suspension. After 30 min, the hypocotyl pieces were removed from the bacterial suspension and placed onto BC-28 callus medium containing 100 µM acetosyringone. The plant tissue and Agrobacteria were co-cultivated for three days at 24°C in dim light.

The co-cultivation was terminated by transferring the hypocotyl pieces to BC-28 callus medium containing 200 mg/L carbenicillin to kill the Agrobacteria, and 25 mg/L kanamycin to select for transformed plant cell

growth. Seedling pieces were included on this medium for three weeks at 24°C under continuous light.

After three weeks, the segments were transferred to BS-48 regeneration medium containing 200 mg/L carbenicillin and 25 mg/L kanamycin. Plant tissue were subcultured every two weeks onto fresh selective regeneration medium, under the same culture conditions described for the callus medium. Putatively transformed calli grow rapidly on regeneration medium; as calli reach a diameter of about 2 mm, they are removed from the hypocotyl pieces and placed on the same medium lacking kanamycin.

5

10

20

35

Shoots begin to appear within several weeks after transfer to BS-48 regeneration medium. As soon as the shoots form discernable stems, they are excised from the calli, transferred to MSV-1A elongation medium, and moved to a 16:8-h photoperiod at 24°C.

Once shoots have elongated several internodes, they are cut above the agar surface and the cut ends are dipped in Rootone. Treated shoots are planted directly into wet Metro-Mix 350 soiless potting medium. The pots are covered with plastic bags which are removed when the plants are clearly growing —after about ten days.

Plants are grown under a 16:8-h photoperiod, with a daytime temperature of 23°C and a nightime temperature of 17°C. When the primary flowering stem begins to elongate, it is covered with a mesh pollencontainment bag to prevent outcrossing. Self-pollination is facilitated by shaking the plants several times each day, and seeds mature by about 90 days following transfer to pots.

The relative content of each of the 7 main fatty acids in the seed lipid was analyzed as follows:

Twenty seeds taken at random from a sample of 25 pods from each plant were ground in 0.5 mL of 2-propanol.

Twenty five µL of the resulting extract was transferred to a glass tube and the solvent evaporated

under a nitrol stream. The dry residue subjected to methanolysis in 0.5 mL of 1% sodium methoxide in methanol at 60°C for 1 hour. The fatty acid methyl esters produced were extracted into 1 mL of hexane and 0.5 mL of water was added to the solvent mixture to wash methanol from the hexane layer. A portion of the hexane layer was transferred to a sample vial for analysis by gas-liquid chromatography as described in Example 3 above. While seven fatty acids were analyzed, only the relative contribution of the 5 main fatty acids to the total are shown in Tables 10, 11 and 12 below.

None of the transformed plants analyzed have fatty acid profiles which are markedly different from that expected in canola seeds. Plants number 129-805, 129-889, and 129-73 are slightly elevated in their saturated fatty acid content and may represent lines with a low amount of over expression. Since the transformation event gives rise to a plant which is heterozygous for the introduced transgene, the seed from these plants is segregating with respect to the 10 transgene copy number. If, as expected, the fatty acid phenotype is additive with respect to the transgene copy number, the full effect cannot be seen in bulk seed population until the second generation past transformation. Further analysis will be done on subsequent generations of plants with modest increases in saturated fatty acid content.

There is no strong evidence for the low palmitate phenotype expected from a co-supressing transformant. In contrast to soybean however, co-supression in canola is a rare transformation event. In our

15

20

experience will other genes in the fatty biosynthetic pathway, as many as 200 transformed lines have been required to observe a strong co-supression phenotype.

westar	4.0	1.7	64.0	19.7	8.5

The average palmitic acid content for the 28 transformants analyzed is 4.3 with a standard deviation of the mean of 0.39. While there are no lines which deviate greatly from the mean in bulk seed analysis, line 130-126 is in exess of 2 standard deviations lower than the mean. Since this could be indicative of a weak antisense phenotype observed in a segregating seed population as described above, 12 single seeds from the plant were analyzed for relative fatty acid content along with 12 single seeds from a non-transformed Westar plant grown in the same growth chamber and planted at a comparable date. The results of those analyses are shown in Table 12.

10

TABLE 12

The relative contribution of 5 fatty acids to total fatty acid content in single seeds from transformant 130-126 and from single seeds of a non-transformed control plant

TRANSFORMANT NO.	FATTY	ACID AS	% OF TOTA	L FATTY A	CIDS

WESTAR4/8	4.12	1.84	60.90	21.19	10.00
WESTAR4/8	3.89	1.69	63.63	19.68	8.99
WESTAR4/8	3.97	1.73	67.68	17.57	6.43
WESTAR4/8	3.97	1.78	63.78	19.47	8.94
WESTAR4/8	3.85	1.76	64.85	18.56	8.65
WESTAR4/8	4.06	1.69	63.74	20.16	8.52

The mean relative palmitic acid content of the 12 seeds from transformant 130-126 is 3.42% and the standard deviation of the mean is 0.359, while the mean palmitic acid content of the 12 control seeds is 4.08 with a standard deviation of the mean of 0.20. The lower mean, greater standard deviation and wider range of observed palmitic acid contents are all indicative of a segregating population in which the seeds homozygous for the antisense transgene for the canola palmitoyl-ACP thioesterase produce slightly less palmitic acid. The observed phenotype will be confirmed by analysis of bulk seeds from multiple plants in the next generation.

As stated for the sense construction above, the occurrence of maximally altered fatty acid phenotypes are rare transformation events in canola. Thus, the phenotype of the low palmitate segregating seed in transformant 130-126 is indicative that the antisense under expression of palmitoyl-ACP thioesterase in canola seeds is capable of decreasing the production of saturated fatty acids but does not indicate the minimum palmitic acid content which may be achieved by this method.

WHAT IS AIMED IS:

- 1. An isolated nucleic-acid fragment comprising a nucleotide sequence encoding a plant acyl-ACP thioesterase wherein said thioesterase has substrate specificity for a C16 acyl-ACP and catalyzes the hydrolysis of palmitoyl, stearoyl and oleoyl-ACP thioesters and demonstrates at least 75% homology to the DNA sequences encoding the mature functional protein corresponding to nucleotides 506 to 1477 of SEQ ID NO:1 or 273 to 1226 of SEQ ID NO:2 or nucleotides 481 to 1438 of SEQ ID NO:31.
 - 2. An isolated nucleic acid fragment comprising a nucleotide sequence encoding the soybean seed acyl-ACP thioesterase cDNA corresponding to the nucleotides 1 to 1688 of SEQ ID NO:1.
 - 3. An isolated nucleic acid fragment comprising a nucleotide sequence encoding the canola seed acyl-ACP thioesterase cDNA corresponding to the nucleotides 1 to 1483 of SEQ ID NO:2.
- 4. An isolated nucleic acid fragment comprising a nucleotide sequence encoding the canola seed acyl-ACP thioesterase cDNA corresponding to the nucleotides 1 to 1674 of SEQ ID NO:31.
- 5. An isolated nucleic acid fragment of Claim 2
 wherein the said nucleotide sequence encodes the
 catalytically active soybean seed palmitoyl-ACP
 thioesterase enzyme corresponding to nucleotides 506
 to 1477 of SEQ ID NO:1.
- 6. An isolated nucleic acid fragment of Claim 3 wherein the said nucleotide sequence encodes the catalytically active canola seed palmitoyl-ACP thioesterase enzyme corresponding to nucleotides 273 to 1226 of SEQ ID NO:2.
- 7. An isolated nucleic acid fragment of Claim 5
 wherein the said nucleotide sequence encodes the
 catalytically active canola seed palmitoyl-ACP
 thioesterase enzyme corresponding to nucleotides 481
 to 1438 of SEQ ID NO:31.

WO 96/06936 PCT/US95/10627

8. A deneric gene capable of transcrining a plant cell of an oil producing species comprising a nucleic acid fragment of Claim 1 operably linked to suitable regulatory sequences, in antisense orientation, producing antisense inhibition of seed palmitoyl-ACP thioesterase wherein said inhibition results in lower-than-normal levels of saturated fatty acids.

5

20

- 9. A chimeric gene capable of transforming a

 10 plant cell of an oil producing species comprising a

 nucleic acid fragment of Claim 1 operably linked to

 suitable regulatory sequences, in a sense orientation,

 producing sense elevation or co-suppression of seed

 palmitoyl-ACP thioesterase wherein said inhibition

 15 results in lower-than-normal levels of saturated fatty

 acids.
 - 10. A chimeric gene capable of transforming a plant cell of an oil producing species comprising the nucleic acid fragment of Claim 2 operably linked to a suitable regulatory sequence, in antisense orientation, producing antisense inhibition of seed palmitoyl-ACP thioesterase.
 - 11. A chimeric gene capable of transforming a plant cell of an oil producing species comprising the nucleic acid fragment of Claim 2 operably linked to a suitable regulatory sequence, in a sense orientation, producing sense elevation or co-suppression of seed palmitoyl-ACP thioesterase.
- 12. A chimeric gene capable of transforming a plant cell of an oil producing species comprising the nucleic acid fragment of Claim 3 or 4 operably linked to a suitable regulatory sequence, in antisense orientation, producing antisense inhibition of seed palmitoyl-ACP thioesterase.
- 35 13. A chimeric gene capable of transforming a plant cell of an oil producing species comprising the nucleic acid fragment of Claim 3 or 4 operably linked to a suitable regulatory sequence, in a sense

orientation, producing sense elevation r cosuppression of seed palmitoyl-ACP thioesterase.

- 14. The chimeric gene of Claim 8 wherein said plant cell of an oil producing species is selected from the group consisting of soybean, rapeseed, sunflower, cotton, cocoa, peanut, safflower, and corn.
- 15. The chimeric gene of Claim 9 wherein said plant cell of an oil producing species is selected from the group consisting of soybean, rapeseed, sunflower, cotton, cocoa, peanut, safflower, and corn.
- 16. A plant cell transformed with the chimeric gene of Claim 8.
- 17. A plant cell transformed with the chimeric gene of Claim 9.
- 18. The plant cell, as described in Claim 16, wherein the plant cell is selected from the group consisting of soybean, rapeseed, sunflower, cotton, cocoa, peanut, safflower, and corn.

- 19. The plant cell, as described in Claim 17, wherein the plant cell is selected from the group consisting of soybean, rapeseed, sunflower, cotton, cocoa, peanut, safflower, and corn.
- 20. A method of producing plant seed oil containing lower-than-normal levels of palmitic and 25 stearic acids comprising:
 - (a) transforming a plant cell with a chimeric gene of Claim 8,
 - (b) growing fertile plants from said transformed plant cells,
- 30 (c) screening progeny seeds from said fertile; plants for the desired levels of palmitic and stearic acids, and
 - (d) crushing said progeny seed to obtain said plant seed oil containing lower-than-normal levels of palmitic and stearic acids.
 - 21. A method of producing oils from plant seed, containing higher-than-normal levels of palmitic and

WO 96/06936 PCT/US95/10627

stearic acids r containing lower-than-no. 1 levels of palmitic and stearic acids comprising:

(a) transforming a plant cell of an oil producing species with a chimeric gene of Claim 9,

5

- (b) growing fertile, sexually matureplants from said transformed plant cells of an oil producing species,
- (c) screening progeny seeds from said fertile plants for the desired levels of palmitic and stearic acids, and
- (d) crushing said progeny seed to obtain said oil containing higher-than-normal levels of palmitic and stearic acids.
- 22. A method of producing soybean plant seed oil containing lower-than-normal levels of palmitic and stearic acids comprising:
 - (a) transforming a soybean plant cell with a chimeric gene of Claim 10,
- (b) growing fertile soybean plants from20 said transformed plant cells,
 - (c) screening progeny seeds from said fertile; soybean plants for the desired levels of palmitic and stearic acids, and
- (d) crushing said progeny seed to obtain 25 said soybean plant seed oil containing lower-thannormal levels of palmitic and stearic acids.
 - 23. A method of producing oils from soybean plant seed, containing higher-than-normal levels of palmitic and stearic acids or containing lower-than-normal
- 30 levels of palmitic and stearic acids comprising:
 - (a) transforming a soybean plant cell of an oil producing species with a chimeric gene of Claim 11,
- (b) growing fertile, sexually mature
 35 soybean plants from said transformed soybean plant
 cells of an oil producing species,

screening progeny seeds om said fertile soybean plants for the desired levels of palmitic and stearic acids, and

- (d) crushing said progeny seeds to obtain said oil containing higher-than-normal levels of palmitic and stearic acids.
 - 24. A method of producing rapeseed plant seed oil containing lower-than-normal levels of palmitic and stearic acids comprising:
- 10 (a) transforming a rapeseed plant cell with a chimeric gene of Claim 12,
 - (b) growing fertile rapeseed plants from said transformed plant cells,
- (c) screening progeny seeds from said

 15 fertile; rapeseed plants for the desired levels of palmitic and stearic acids, and
 - (d) crushing said progeny seed to obtain said rapeseed plant seed oil containing lower-than-normal levels of palmitic and stearic acids.
- 25. A method of producing oils from rapeseed plant seed, containing higher-than-normal levels of palmitic and stearic acids or containing lower-than-normal levels of palmitic and stearic acids comprising:
- 25 (a) transforming a rapeseed plant cell of an oil producing species with a chimeric gene of Claim 13,
 - (b) growing fertile, sexually mature rapeseed plants from said transformed rapeseed plant cells of an oil producing species,
 - (c) screening progeny seeds from said fertile rapeseed plants for the desired levels of palmitic and stearic acids, and

- (d) crushing said progeny seed to obtain 35 said oil containing higher-than-normal levels of palmitic and stearic acids.
 - 26. The method of Claim 20 wherein said plant cell of an oil producing species is selected from the

WO 96/06936 PCT/US95/10627

group consisting of soybean, rapeseed, subserver, cotton, cocoa, peanut, safflower, and corn.

- 27. The method of Claim 21 wherein said plant cell of an oil producing species is selected from the group consisting of soybean, rapeseed, sunflower, cotton, cocoa, peanut, safflower, and corn.
- 28. The method of Claim 20 wherein said step of transforming is accomplished by a process selected from the group consisting of Agrobacterium infection, electroporation, and high-velocity ballistic bombardment.

10

- 29. The method of Claim 21 wherein said step of transforming is accomplished by a process selected from the group consisting of Agrobacterium infection,
 electroporation, and high-velocity ballistic bombardment.
- 30. The isolated nucleic-acid fragment of Claim 1 wherein said thioesterase demonstrates at least 81% homology to the DNA sequences encoding the mature 20 functional thioesterase protein corresponding to nucleotides 242 to 1492 of SEQ ID NO:1 or 273 to 1226 of SEQ ID NO:2 or 481 to 1438 of SEQ ID NO:31.
 - 31. An isolated nucleic-acid fragment encoding a soybean acyl-ACP thioesterase according to the amino acid sequence of SEQ ID NO:29.
 - 32. An isolated nucleic-acid fragment encoding a rapeseed acyl-ACP thioesterase according to the amino acid sequence of SEQ ID NO:30.
- 33. An isolated nucleic-acid fragment encoding a 30 rapeseed acyl-ACP thioesterase according to the amino acid sequence of SEQ ID NO:32.

Interr 1al Application No PCT/US 95/10627

A. CLASSIFICATION OF SUBJECT M. 1907 1PC 6 C12N15/55 C. 5/8%

C12N5/10

A01H5/00

1B1/00

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols) IPC 6 C12N A01H C11B

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

C. DOCU	MENTS CONSIDERED TO BE RELEVANT	
Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
χ .	PLANT PHYSIOL. BIOCHEM., vol. 31, 1993 pages 599-602, GRELLET, F., ET AL. 'Arabidopsis thaliana systematic cDNA sequencing reveals a gene with homology with Umbellularia californica C12:0-ACP thioesterase' see the whole document	1,30
P,X	WO,A,95 13390 (CALGENE INC ; VOELKER TONI ALOIS (US); YUAN LING (US); KRIDL JEAN () 18 May 1995 see figures 2,12	1,9,30

Y Further documents are listed in the continuation of box C.	Patent family members are listed in annex.
* Special categories of cited documents: A document defining the general state of the art which is not considered to be of particular relevance E earlier document but published on or after the international filing date L document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified) O document referring to an oral disclosure, use, exhibition or other means P document published prior to the international filing date but later than the priority date claimed	"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention "X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone "Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art. "A" document member of the same patent family
